Some of the tests to which steel may be snhjected in order to determine its merits may he mentioned, although it is somewhat difficult to describe the indications by which an opinion is formed. They can he acquired only hy practical experience. In the case of what is known as hlister steel it may he generally considered as of the best quality when the blisters are somewhat inferior in sizs. Where there are hnt few hlisters, and tbose of an irregular size, it is safe to pronounce the steel of an inferior quality. What is sometimes called natural steel, German steel and cast steel are always had, if siogle sparkling crystals show themselves in a fresh fracture. Generally speaking, any sparkling steel is had. It is merely hard, impure iron. A good quality of hardened steel on fracturing presents a dead silvery appearance, and is of an inferior white color. In soft shear steel, the fracture has a hluish tint, and in soft cast steel, it is of a grayish hue. In German steel and natural steel, the fracture has a soft, bright, gray tint, often inclined to fracture in the center of the har. Of course, the proof of the pudding is in the eating of it, and an actual test of the steel in hand is a much more satiefactory way of determining its quality than any examination of its appearance hefore working.—*Blacksmith and Wheelwright.*

SCIENTIFIC PROGRESS.

Advance in Photography.

Recent advanoea in photography bave not only enabled us to produce plates that are very mnch more seasitive to light than any previously known, but the processes bavo bsen so simplified that the tonrist can easily carry with him all the artioles necessary to field photography in a very compact and convenient form. Formerly it was neoessary to carry a stock of chemicals and some apparatus, aad the plates had to be prepared and made sensitive on the spot. Now, however, dry platea can be purohased, at a reasonable cost, whicb will ksep for any length of time, and whioh are ready to receive the impression in the camera at any moment. Moreover, thoy are far more sensitive than the ordinary collodion plates in commoa nso, and are particularly suitable for landscape work. All that is necessary now for the tonrist to carry witb him is a small oamera aad a set of the dry "gelatino-bromide" plates. The exercise of good taste and judgment will enable the amatenr to obtain most excsllent results in landscape photography.

The value of the dry process for soientifio explorations cannot he overestimated. The process of preparing the gelatino-bromine plates is very simple. A solution of gelatine is first prepared, to which a small quantity of bromide of potassinm is added. A solution of nitrate of silver is than poured in, in a dark room, and the whole is maintained at a moderate temperature from one to four days, in order to render the mixture very sensitive to light. Glass plates are then coated witb the solntion, driad thoroughly, and kept in the dark nutil they are exposed in the camera. It is hardly premising too much to say that the gelatine process will he the principal process of the fnture, for already it is hscoming very popular. However, for very fine work, such as glass positivss, that require very sharp lines and clear lights, photographers must prepare their own plates, for those that are sold are not always carefully made. Among the improvements in paper prints the platinum process deserves especial mention, owiag to the excellence of the results and their permanence. The dark parts of the prints are of metallic platinum in a very finely divided condition. Such prints can never fade or lose any of their original brilliancy.

Fertilizer Experiments.

In the discussion on fertilizsrs, at the recent meeting at Newtown, Conn., Mr. Sedgewick, of Cornwall, said he thought that Dr. Atwater's experiments had saved the farmers a great amount of money hy tsaching fertilizer manufacturers that less nitrogen is required for many crops than had formerly been supposed. Nitrogen is the most costly ingredient used in commercial fertilizers, and the most difficult at the present time to ohtaia. It would he wasteful, therefore, to use a greater qnantity than is really needed, and such waste is exceedingly costly to the farmer. As it is found that less nitrogen is required, the price of fertilizers has been gradnally droppiag in market, and this gain is greatly to the benefit of the farmer. It enables him to huy more, and to nse more with a fair prospect of ohtaining a profit. One objection to the use of guano, he believed, was that it contains a larger percentage of nitrogen than is needed, and consequently a larger proportion than farmers can afford to pay for. A saving of 1% in the amount of nitrogen in a ton of fertilizsr will cheapan the cost about $4. He thought the most profitable way to use fertilizers is in connection with stable manure, the fertilizers bsing compounded in snch a way as to make the manure and fertilizsr together just meet the wants of the crops to he grown. Exactly how the nitrogen is taken by plants, he did not attempt to explain, hut it is evident that soil which is well filled with the tops and roots of clover and other plants contains a large amount of nitrogsn that the growing crop will in some way appropriate.—*New England Farmer.*

Effect of Electric Lighting on the Demand for Gas.—The *Journal of Gas Lighting*, in a review of the past year, says: "Perhaps the most positive and ahiding result of the rage for electric lighting in public streets is the increase of gas consumption which inevitably follows the removal of the electric lamps, or is insisted upon in districts adjacent to those occupied hy the electricians. The old style of street lightiug, with five foot burners, or even worse, will no longer satisfy the puhlio in husy thoroughfares. More light is demanded even from gas, and there is consequently a large and growing use for high-power gas burners. It is fortunate for the intereste of gas ligbting that the opportunity has not been allowed to pass fruitlessly hy the manufacturers of gas lamps. Numerous inventors, such as Herr Frederick Siemens, Messrs. Sugg, Bray, Wigham, and, latest of all, Mr. Douglass, bave demonstrated that the modern demand for better means of lighting is capahle of being amply satisfied by ordinary coal gas alone. Whether electric lighting eventually succeeds in eatablishing itself or not, it is certain that it has given a great impetns to tbe business of gas ligbting in the past year."

Oxygen as a Source of Energy.

As is well known, the higheat temperatures are obtsinedhy combustion—that is, by the combination of other hodies with oxygea. Since oxygen is contiaually inhaled and oonsnmed by animals during life, we are ohliged to consider this as the source of heat and force. We have here a problem which is open to discussioa, namely, whether the energy liberated hy the combustion was originally contained in the oxygen or in the other substances. It appears as if the latter assumption was generally acceptcd; at least, statements are oftea met with, snch as, for iastance, that coal contains the heat of the sun which has hsen stored up during thousands of years. Although we cannot at present, with the means at our disposal, defiaitely solve this problem, it can at least ho shown that the statement has little in its favor. The dscomposition of carhonio acid by the influence of the light and heat of the sun is effected in such a manaer that the carhon is employed in the formation of the compouads of which the plant is hnilt up, while the oxygen escapes into the atmosphere. Now, we know that solids contain the least energy, becaass it must be supplied to them in the form of heat in order to convert them into the liquid or gaseous state, while on the contrary, heat mnst he withdrawn from gases to condense them to liquids or solids. Oxygen is oae of the most permanent gases, and must therefore possess an enormous amount of energy, while carhon, on the other hand, heing one of the most difficultly diffusible and volatile hodies, can oaly contain a little energy. This makes it extremely probahle that the force of the sun, taken up hy the plants, is not stored in their hodies, hut in the free oxygen of the atmosphere. Hence the latter is to be considered as the iaexhaustihle source of power on wbich man and animals draw, and in the carhon we possess a valuahle aid for making this energy, contained in the oxygen, available.—*Popular Science Monthly.*

Electrical Ball Finding.—Prof. Bell has snhmitted to the Paris Academy another electric method (in addition to that of the induction halance) for detecting a projectile in the human hody. It consists in inserting a fine needle near where the hall is supposed to he. This needle heing connected by wire with one terminal of the telephone, while a metallic plate laid on the skin is connected with the other terminal, when the point of the needle reaches the hall a current arises (the ball and the metallic plate naturally forming a couple), and a sound is heard in the telephone. The needle may he inserted in several places with little pain, and the pain may be prevented hy means of ether spray. The method has been tested on a piece of beef containiag a ba'l. Contact of the needle with hone gave no sound, hut there was a distinct sound whenever the hall was reached. The arrangement may he modified hy introducing a vihrator into the circuit; a musical sonnd is then heard when the needlo meets the hall. The circuit may also comprise a weak battery. In this case there is a sound from the moment the needle enters the skin; hut at contact witb tbe ball, the sound is greatly intensified.

A Fog Bow Before Sunrise.—The phenomenon of the ordinary rainhow is familiar to every observer of nature. White fog-hows, or "fog-eaters," as they are called hy the sailors, are frequently visihle in localities favorable for their formation; and they are generally regarded as indications of clearing weather. "A fog-how was observed," writes Mr. H. C. Hovey, "on the morning of the 8th of January, from my residenca on Fair Haven hights, near New Haven, Conn., at the moutb of the Quianipiac river, and about 100 ft. above the sea level. No rain was noticeable in any quarter, but the valleys were filled with fog, ahove which the billtops stood like islands. At exactly ten minutes hefore sunrise (due at 7:26 A. M.), on looking northwest I saw a hrilliant arch of prismatic colors spanning the East Rock range, the highest point of which is 350 ft. above the sea. As the sun arose the arch diminished in hight and vividness, and hy the time the orh was visihle in tbe morning sky, the fog-bow had vanished."

Wet and Dry Thunderstorms.—A correspondent of the London *Times*, writing from tbe Transvaal, South Africa, says: "Every afternoon tremendous storms of thunder and lightning hurst upon us. These were of two kinds, the wet and the dry. The first is harmless, though noisy; the second exceedingly dangerous. During the dry thunderstorms, which were prevalent toward the end of October, the lightning seemed quite stupefying. It was unaccompanied hy either wind or rain. The angry flashee were followed almost simultaneously by awful crashes of thunder, which esemad to shake the earth. One or two tents were struck, and the grass was set fire to in several places within sight of our camps, hut no life was lost, only some arms damaged. The dry thunderstorms were soon followed by wet ones. The rain, mixed up with enormous hailstones, soused the thirsty earth, and every ltttle crack on the veldt hore its hurden of water to the Vaal, which rose and hecame impassahle."

A series of expariments are in progress at Portsmouth, England, in order to determine the dynamo-electric machino for the working of "search" lights on board of war vessels.

Mining Share Market.

"Not mnch doing in stocks" has got to he snch a common expression that people are tired of hearing it. Yet we mnst repeat it this week. The shntting down of work at the Forman shaft in the Comstock is the most notahle event affecting stocks, thongh it is hoped that this snspension of operations at that point will he of short dnration.

The sump of the hig C. & C. winze, on the California and Consolidated Virginia line, has been completed, and a station is now being cut ont in it at the 2700 level. When this station is completed a drift will he startsd north to connect with that going sonth from the Ophir on the same level.

The Overman folks will continne their prospecting operations on their 2275 level, and it is to he hoped that they may make a strike that will cause the other companies to resnme work in earnest at an early day.

At the sonth end a drift is heing rnn into Jnstice ground on the 2150 lsvel of Alta, and also from the same point northward into the Benton gronnd. Work will also soon he resnmed in the face of the east drift, 2150 level.

Down at Bodie, according to the *Free Press*, mining operations during the past week have progressed mnch the same, with a decided tendency to improve. On the 100 level of the Standard indications are more than favorable; indeed on the street rnmors prevailed that a very favorable hody of ore had hsen strnck at that point, hnt these rumors conld he traced to no reliahle sonrcs. The feeling, however, of the camp is that we are on the eve of some very favorahle developments. They continne crosscntting on the 1,000 level of the Standard and the resnlt of this work will be awaitsd with interest. On the 25th instant crosscntting will he commenced on the 750 level of the Oro, and great confidence is felt that this work will nncover something valnable. On the 800 level of the Lent shaft crosscntting is in progress. In this work, also, much interest is felt. Work is progressing favorably in the Tioga Con., and, in fact, all the mines from which there hasheen reason to expsct anything, seem to he doing decidedly favorahle work.

THE Truckee *Republican* says the pressnt season has heen the most favorahle for logging for many years. An immense amount has heen cnt, and qnite an army of men and teams have heen employed on the Little Truckee.

Hot Water in Mines.

In some of the mining regions of this coast the greatest difficnlty with which the camps have to contend is lack of water. In some places the mills have to he placsd many miles from the mines, and considerahle expense entailed in hanling ore, owing to lack of water at the mines themselves.

At other places, again, just the opposite difficulty is met with. The mines are so wet that all the profits are swamped in the efforts to free them of water. Probahly at no other place has this heen so apparent as on the Comstock. The amount of water that has to he raised is enormons, almost heyond the conception of those not familiar with snch matters. Heavy and expensive pnmping machinery, with all the ingenions adjnncts, improvements and appliances for effectiveness and economy which can he devised, are in nse on these mines. In addition, one of the longest tunnels in the world has been rnn at very heavy cost to tap the mines.

Water at ordinary temperatnre is had enongh, hnt when it is met with so hot as to scald anyone tonching it, the difficnlties are greatly enhanced. An illnstration of this is shown in making the recent Savage connection. The upraise was started a little south of the month of the incline so as not to interfere with the drill-hole that was draining the watsr. In this way the hot water was avoided and tolerable good progress made. When near the point of connection the hole had to he tnrned, of course, to meet the incline. The scalding hot water was then encountered and from that time it has been necessary for the workmen to stretch a canvas overhead to catch the dropping water before a hole is started. This consnmes time. When the holes are charged it is necessary to fire them at once to keep the water from washing the explosives ont, and the canvas covering is hlown ont along with the rock. Before work can be resnmed the same steps have to he taken so that ahont 24 honrs elapse hetween the firing of charges. It is mining under difficnlties.

A GENTLEMAN from Sutro says times are very dnll there. A nnmher of families are moving away. Others only remain in hopes that at the annual meeting of the Tunnel Co., which occnrs March 6th, orders will he issned to drive the tunnel throngh Mt. Davidson. Shonld this not he done, two-thirds of the inhahitants of the place intend leaving.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

BUTTE.

NOTES.—Orovillc *Mercury*, Feh. 17: Messrs. Brock & Taher are now the owners of the celehrated Banner mine, together with the mill and hoisting works, they having purchased it from Burke & Kenney. The property is estimated to he worth $50,000, and is probahly one of the richest quartz mines in this county.

BIG BEND.—The Big Bend Tunnel M. Co. is being pnshed forward at a rapid rate. The company was formed in Buffalo, New York, and the following officers were elected: Ray V. Pierce, President; Geo. H. Van Vleck, Vice President; James H. DeGraf, Tressurer; Jas. A. Roherts, Secretary; N. A. Harris, of this city, Resident Agent. Major McLaughlin and Col. Logan left for Europe on the 14th day of this month for the purpose of getting foreign capital to invest. For this purpose they will visit London and Paris. The company voted them $20,000 to defray their expenses on the trip. Waldemar Allstrom has sold out and now has no interest in the company. Mr. Ed Harkness is the accountant in this city.

TREASURE BOX.—The Treasure Box mine, situated just across the river, is working night and day, running their tunnel into Table mountain. They are now in at the present time about 2,200 ft. This distance brings them under the bench which lies next to the mountain, and they are therefore not under the main mountaio. The face of the tunnel is in pipe clay and gravel. The gravel is spotted, sometimes prospecting rich and at others very low.

CALAVERAS.

SHAFT.—*Mountain Echo*, Feh. 14: David Findley & Co. are at present sinking a shaft on the Doc. Hill mine. The veiu is about 5 ft in width, and the ore prospects well. They have now on hand over 20 tons of quartz that has the appearance of being rich.

WORKING ORDER.—We paid a visit to T. L. Lindsay & Co.'s mine the other day and found everything in working order. The main shaft, in which work is being done, is 7x3½ ft in the clear, is about 45 ft deep, and is one of the best timhered shafts in the country. This mine is situated one mile west of Angels, and was known in former years as the Antone claim; it has heen owned, however, by the present proprictors for a number of years, and has yielded them an immense revenue. If energy and perseverance is of any importance, the present company will succeed.

OSBORN.—We called upon the proprietors of the Osborn mine the othcr day at Smith's flat, and found one of them busily at work. He showed us some fine specimens of rock which he had taken out that day. The mine is looking well.

THE owners of the Black Oak mine have finally completed their preparations, and are now ready for more extensive operations. This mine, as before stated, is situated about 3 miles northwest of Angels, and owned hy Osborn & Fisher. It is, perhaps, one of the richest mines in this section.

RASPBERRY MINE.—Work is still going on this mine, hut, as there has heen no clean-up made recently, nothing of importance can be said of it. Work on the Bovce mine still continues.

MCELROY MINE.—Supt. Eudy, of the McElroy gravel mine, is working away, making preparations to work the mine properly.

EL DORADO.

NEW MILL.—Amador *Ledger*, Feh 17: Knight & Co. have just shipped all of the machinery for the 10-stamp mill to he put up near Placerville, El Dorado county. The hauling was done hy teams from El Dorado, and required 5 or 6 heavily loaded teams. The same firm has also sent out recently a water wheel for the Church Union mine, in El Dorado county. H. G. Murray has goue there to put the machinery in position.

STAMPS AFTER ALL.—Georgetown *Gazette*, Feh. 17: The Eureka has shut down. This sounds like had uews. Indced it does. But hold! You want to know why it has shut down, and whether it is only temporary. The *Gazette* has frequcntly told its readers that the Eureka was a good mine, comprising an immense hody of ore from 12 to 20 ft in width, and would yield upon an average of about $6 per ton in free gold, not counting the sulphurets, which will yield enough more to swell the yield of the ore to at least $12 per ton. The mine has shut down simply hecause the new mill wore itself out after grinding about 100 tons of ore. The new candidate for trial did admirably good work on the first 50 tons, and both Mr. Baird and the operator, Mr. Powning, were pleased with the working and the good resulta obtained. But Mr. Baird now joins in the opinion entertained by the most eminent and practical quartz mon of California, that the common stamp mill is the boss, and, accordingly, the Eureka will he supplied with a good stamp mill at an early day. How many batteries will he put up at first wo have no authority for stating; hut we helieve that not less than 40 stamps will enliven that end of town before the end of the approaching summer. Mr. Baird makes no hlow of what his company is going to do. What he says is emphatic, and, we helieve, reliahle.

DEL NORTE.

HAPPY CAMP NOTES.—Del Norte *Record*, Feh. 11: The winter thus far has proved very unfavorahle for the mining population with few excep.ions, and as the prosperity of Happy Camp depends upon the amount of gold-dust extracted from the hanks—gravel hanks 1 mean, not savings hanks—why, all that is essential is plenty of water and systematic application. The miners commenced to work on the 27th day of December, and continued their vocation until the 4th or 6th inst., with but few exceptions; for want of the one thing needful—water—ceasing operations. Since the 6th till the prescut time the weather has heen delightful; frosty mornings and a clear, bright sky, dotted here and there with a whitn cloud in keeping with this time of year.

INYO.

PANAMINT.—*Independent*, Fch. 18: With the halance of the hullion from the month's run of the hig mill at Panamint, amounting in all to ahout $24,000, Supt. Phehy has gone to San Francisco. The company is still working the Wyoming mine and has lessed several others to chloriders, who are getting out rich ore for another run.

THE JEANNETTE.—Harry Wright and Henry Malone have heen working an old gold ledge near Fish Springs, and are elated over the developments.

MARIPOSA.

COULTERVILLE ITEMS.—Cor. Mariposa *Gazette*, Feh. 18: I am informed by a reliable gentleman, who has the means of knowing, that the mode of working the Black hill ore has proved a success; which is to he followed up hy a test on hard ore taken from the Champion mine, owned by Mentzer & Co. If the same method results as favorably in hard quartz as it does in talc, it will completely revolutionize the present mode of milling quartz rock:

NEVADA.

LEAD ORES.—Grass Valley *Union*, Feh. 16: Wm. Gay, who is interested in a miuing location called the Mammoth, which is about one mile northwest of Spenceville, brought to town yesterday a number of pieces of ore from the claim which were remarkably heavy in lead. This was taken out within 4 ft of the surface of the ground. There were no assayers or experts here to prove whether the ore contained silver, hut appearances favored the helief of the presence of that valuahle metal. The great copper helt runs through the foothills at Spenceville and vicinity, and these lead ores are in the same geological formation. Some of the veins prospect in gold,

but are not rich in that precious metal. The region to the north and south of Spenceville is rich in copper ores, and lead and silver may yet be found in quantity to prove profitable for working, as the specimens seem to indicate.

WASHINGTON MINE.—Grass Valley *Tidings*, Feb. 18: Work at the Washington mine has been stopped for a week or so, partly on account of a scarcity of water, and partly for repairs and improvements on the big wheel. A new wheel is being made, with other castings, in San Francisco, and will be shipped here as soon as they are completed. The large water wheel will be so arranged and improved upon as to give more power and better satisfaction. As soon as the roads become good, so that wood may be hauled, active work will be resumed.

FORD AND MULLEN MINE.—We were to day shown 8 candle boxes filled with specimen rock which came from the Ford and Mullen mine. The rock glitters with gold. Two boxes of it, which were taken out last evening and deposited in J. F. Judd's vault, are valued at $1,950. Thirty lbs of specimen rock was recently sold by the company to San Francisco parties for $1,910 25. The mine is looking as well as ever, and every few days a box of valuable specimen ore comes out. It was pay day for employees of the company to-day, when all hands were paid off at the store of James F. Judd, in Boston ravine.

PLACER.

RICH QUARTZ.—Placer *Times*, Feb. 18: Tuesday we were shown some quartz specimens by Capt. Anderson that were very rich with free gold. They came from a ledge on Rock creek, about 2 miles this side of Auburn station, which Anderson and two other men located last October. The main vein can be traced several hundred ft by the croppings on the surface, and, so far as examined, the rock, mainly, is very rich. The specimens shown us, it is judged, would go about $1,000 to the ton. A lot of 52 lbs of the rock, not so rich as the specimens we saw, were pounded up in a mortar and $28 was the amount cleaned up. The shaft is down 15 ft and the rock all contains gold visible to the naked eye. Capt. Anderson has been hunting for a strike like this for a long time, and we are glad he has at last found so rich a prospect. The ledge will be worked in the spring extensively.

PLUMAS.

ROUND VALLEY.—Greenville *Bulletin*, Feb. 15: W. E. Adams states that he crushed 400 pounds of rock from the ledge lately found by him at Round Valley, and got about $7.50. The rock was crushed in a hand mortar under very disadvantageous circumstances.

PROPERTY SOLD.—The personal property of the Plumas National mine was sold at auction on Saturday, at the mine. The real estate was sold at the Court house in Quincy, on Monday. No report has been received of the prices obtained. It is said that the affairs of the company will now be settled up and the mine and mill put in operation again as soon as spring opens.

SIERRA.

EXTENSION.—Sierra County *Tribune*, Feb. 17: The Bald Mountain Extension Co. cleaned up 87 ounces of gold last Sunday as a result of one week's washing. The air shaft of the Bald Mountain mine filled up last Saturday, thereby necessitating suspension of work until Monday afternoon.

SIERRA CITY.—Our town has been lively since pay day of the Marguerite and Sierra Buttes quartz mines, the former having paid on the 7th inst., and the latter on the 5th inst. Our mining interests are assuming a favorable outlook for the future, and great preparations are being made for spring work. The Marguerite Co. is taking out the richest ore of any mine in this section. It is immensely rich. The Haskell Peak Oravel Co. is running in cement and quartz gravel. At the Blue Oravel mine they are raising an air shaft and running the main tunnel ahead. Work is progressing steadily at the 1001 gravel mine. The hydraulic gravel mining companies are not working along the river on account of the cold weather.

GOOD HOPE.—*Mountain Messenger*, Feb. 18: Mr. Cunningham, Secretary of the company that owns the Good Hope quartz mine, was up this week and satisfied all the liens that had been filed against the property. The whole sum was only some $2,200. It is said that the mill will be started as soon as the weather will permit. The company has about 100 tons of rock in the dump house, but will not be able to get down any more until the weather is more favorable.

GOOD HOPE EX.—Wm. Messerve is running a tunnel on the Good Hope Extension, and expects to strike the ledge at a depth of 100 ft in a week or two. There is very good rock on the croppings of this ledge, which lies next north of the Good Hope.

TUOLUMNE.

SULPHURETS.—Tuolumne *Independent*, Feb. 18: It does not pay to ship sulphurets or concentrations that will go less than $30 per ton; although it will pay miners to save them, however low the grade may be, for in the "high future" furnaces will be erected in this county that will work almost anything with a profit in that line; and the storage of such material costs nothing, until such time arrives.

GRAVEL.—Freels & Co. have leased Mr. Kelley's lot, opposite Sonora foundry, for mining purposes, where they have struck a rich gravel bed—having demonstrated the fact by a shaft. They will now proceed to tap the diggings by a tunnel under the road for the purpose of hydraulic mining, if necessary. Only a portion of the rich spots in and around Sonora have been discovered.

NEVADA.

WASHOE DISTRICT.

CALIFORNIA.—*Enterprise*, Feb. 16: On the 1050 and 1750 levels are clearing out and repairing the drifts and winzes connecting with the old Con. Virginia shaft.

CON. VIRGINIA.—On the 1050 and 1750 levels are cleaning out and repairing drifts and winzes connecting with the old Con. Virginia shaft.

SIERRA NEVADA.—On the 2700 level the main north lateral drift has been extended 14 ft, and the joint Union Con. east winze has been sunk and timbered 6 ft.

ALTA.—Since last report the north lateral drift on the 2150 level was extended 31 ft, and the lateral drift south 31 ft. The west drift was extended 40 ft; total length, 837 ft. The drain drift on the 1250 level is completed, and the water in the lower levels of the Justice is draining off. Rock hoisted, 526 cars; wood consumed, 80 cords; strokes made by pump, 37,000.

YELLOW JACKET.—No work has been done in the mine since the morning of the 12th instant, at which time a large flow of water came to our shaft from the Imperial group of mines, and which has since continued, filling our 3000 and 2328 levels, and this morning the water stands 5 ft deep on our 2700 level station. We are pumping and bailing an average of 102 miners' inches per 24 hours. When the water reaches the 2560 level of the Belcher and Crown Point mines, their pumps will assist in handling the same. The water is said to come from a quartz body cut in the Exchequer mine, 2800 level, our 2700 level, and which will no doubt require 30 days or more to drain.

OPHIR.—On the 2700 level the main south drift has been extended 30 ft. On the 1700 level are repairing joint California east crosscut.

UNION CON.—On the 2700 level the main north lateral drift has been extended 26 ft and the main south lateral drift 36 ft.

BARBEE DISTRICT.

THE MINES.—Cor. *Silver State*, Feb. 10: Barbee district is situated on the eastern slope of the Humboldt range, 4 miles from Humboldt House, on the C. P. R. R. Prominent among the mines of the district, which have been prospected to any extent, is the Silver Belle, which is being opened by an incline shaft that has reached a depth of 85 ft. This is a free milling ore and can be worked by ordinary mill process to 90 per cent of its assay value. Next in importance is the Tecumseh, which is a very promising prospect. The vein is composed of white quartz, having well-defined walls. The ore carries 80 ounces of silver to the ton, and contains a small percentage of lead. The lead has an average thickness of 2 ft for 125 ft, the distance it has been uncovered on the surface. The Climax and Oro Plata are located on the same vein, and can be traced a distance of 2,000 ft. These properties all belong to Judge Barbee, who is now in Salt Lake, and, will, as soon as the weather settles, increase the working force and push the developments. Lively times may be looked for in the district the coming season.

BELMONT DISTRICT.

BELMONT.—*Courier*, Feb. 11: The draft to our furnaces was rather poor, so we concluded to shut down both furnaces so as to increase the size of the fires under the dry kiln. Also make some improvements on the furnaces, and wait the arrival of two new wheels which will arrive here on Saturday, the 11th inst. Also had some other little repairs to make on steam drum, etc.

BULLION DISTRICT.

LADY OF THE LAKE.—Eureka *Sentinel*, Feb. 10: The Lady of the Lake mine in Bullion district, Lander county, situated 23 miles from Beowawe and about 10 miles from S. Wenban's mine, in Cortez district, has been sold to Eureka parties, the purchasers being Messrs. W. O. Mills, Jr., James H. Mundy, John E. Plater, H. Muller, Wm Arrington and B. C. Levy; the sellers, Messrs. W. H. Du Commun and James Lovie. The price paid for one-half the mine is $8,000. The sellers surrender one-fourth of their remaining interest in consideration of their share of the profits of mining and milling on a one-fourth ownership. The company have leased (with the privilege of buying) a 5-stamp mill, 2 miles from the mine, from which ore is easily transported down the mountain. The mill is situated on a creek, which supplies ample water. Five men have been sent from Eureka to work the mine under Mr. DuCommun, who will act as foreman.

CANDELARIA DISTRICT.

NORTHERN BELLE.—*True Fissure*, Feb. 18: Thirteen feet have been added to the depth of the main shaft during the week; the total distance made to the 13th instant was 65 ft. Within a few days a very encouraging development has been made between the seventh and eighth levels. It is in the west part of the mine, and in new ground. Sufficient work has not yet been done to determine its extent. There is no change in other levels above the adit. Sixty-four tons of ore are being extracted daily and sent to the mill. Bullion shipments for the week ending February 17th, $14,120.45. Shipments on February account to February 16th, $30,470 88.

MOUNT DIABLO.—The east drift on the third level has advanced 16 ft and shows more favorable ground in the face. The stopes above this drift look encouraging and are yielding considerable ore of a very good grade. The stope from the north crescent on this level is looking well. The first level stope continues to turn out a very fair quantity of good ore. A shipment of bullion was made on the 10th instant amounting to $3,501.10, and another on the 14th amounting to $8,822.09.

EAST MOUNT DIABLO.—Arrangements have been made with the Mount Diablo M. and M. Co. for the use of its shaft to work their mine. The east drift on the third level of the last-named property has reached the line between the two mines. The company will now drive the drift into its ground, using the Mount Diablo shaft for hoisting purposes. This will prove the East Mount Diablo to a depth of 400 ft, and some interesting developments may be expected as this work progresses.

SOUTHERN NEVADA.—Work on this mine is progressing with a force of 7 men. During the week the main drift has been driven a distance of 18 ft through a body of rich chloride ore.

PRINCESS.—The guides have been put in the shaft and the cages placed in position, all preparatory to starting up with steam.

CORY DISTRICT.

BIG INJUN.—Esmeralda *Herald*, Feb. 17: The Big Injun mill in Cory district is running successfully. The company contemplate putting in five more stamps next spring.

CRABB DISTRICT.

EAGLE BIRD.—Esmeralda *Herald*, Feb. 17: The Eagle Bird mine is looking well. Mr. Crabb has about 30 tons of ore on the dump, with any amount of rich ore in sight. Lupton's mines, the Dixie and Captain Jack, are showing up well. Messrs. Hernleben, Erway & Horn shipped a four-horse load of ore from their mine in this district to a mill in Six Mile canyon, and had it worked in small lots for a test. One lot worked $700 to the ton.

ESMERALDA DISTRICT.

THE CORTEZ MINE.—*Herald*, Feb. 17: The development in this mine are more encouraging than ever. The ore dumps and chutes are increasing in bulk every day. They must soon get a mill or increase the capacity of their dumps. The southwest drift from the lower tunnel is now extended a distance of about 90 ft, and shows ore in full face which will mill at least $30 per ton, and is daily increasing in quality. Taking all together, the prospects of the mine were never more flattering.

THE UTAH.—Developments in this mine commenced yesterday morning under the management of T. H. Wells, he and L. Richardson having a bond of the same. A force of seven men were put to work on 8-hour shifts of 2 men each, with 1 car man. The work for the present will be prosecuted by extending the northeast drift in the lower level of the Cortez onward in the Utah, which will prospect the latter mine at a depth of 276 ft from the apex of the ledge.

HUMBOLDT M. M. Co.—The finishing touches are being put on the company's mill, and ex-Gov. Blasdel informs us that it will be in complete order for crushing ore on the 1st. There are between 300 and 400 tons of ore on the dump at the mine, with plenty more in sight.

THE CENTENNIAL is turning out the usual amount of rich ore and employing the usual number of men.

LAKE DISTRICT.

LARGE LEDGES.—Esmeralda *Herald*, Feb. 17: There are a number of large ledges in this district which will be prospected next spring. Most of the ore is heavy with lead, and in places is found in quantities near the surface, sometimes very rich in silver.

THE OHIO.—The shaft of the Ohio is now down 60 ft, and shows a vein of pay ore about 12 inches in width in a ledge of about 5 ft. The whole ledge will give good assays. Work, which was suspended a short time ago, will soon be resumed. The owners expect to ship considerable ore next summer.

LIDA VALLEY DISTRICT.

PROSPECTS.—Lyon Co. *Times*, Feb. 18: The Centennial Sapphire Mining Co. has had the claims belonging to it surveyed preparatory to procuring patents. A contract has been let for a shaft to be sunk from the 70 level. The mine is reported as looking well, and it is expected that a mill will be in operation inside of a year. Supt. A. C. Hamilton intends to push operations, and will doubtless soon make the mine justify the reputation it formerly held, of being one of the valuable mines of Nevada. The 5-stamp mill 2½ miles south of Lida has been purchased by Wm. Appleby and ex-Assemblyman Tom Lane, of Storey county. They own several good mines in the neighborhood, and intend working their own ore in addition to doing custom work. They are experienced mill men and will doubtless by the successful working of their mill add much to the prosperity of the camp.

GOLD MOUNTAIN DISTRICT.

STATE LINE.—Esmeralda *Herald*, Feb. 17: The State Line mill at Gold Mountain has been running twenty stamps for the past two weeks. There are 20 men at work in the mine and mill. The mill machinery is of good pattern, nearly all entirely new. No clean-up has yet been made, and the result is therefore not known, but at present everything promises a profitable working.

SANTA FE DISTRICT.

COPPER.—Lyon Co. *Times*, Feb. 18: The Stone Cabin copper mines, in Santa Fe district, which were bonded a short time ago by R. R. Thurman, sent a lot of ore to the Lyon mill and mining company which went over 30 per cent. in copper. A company is incorporating in New York to work these mines, and there is every prospect that they will prove a good investment. There are now 200 sacks of ore, ranging from 30 to 40 per cent. in copper, ready for shipment.

TUSCARORA DISTRICT.

TO BE RE-OPENED.—*Sentinel*, Feb. 18: From a gentleman in Eureka, who has come here from Tuscarora in the last few days, we learn that negotiations are on foot to re-open the Grand Prize and Argenta mines. Those to whom the Grand Prize Co. is in debt to allow them to resume operations and wait for payment out of the proceeds of the working. This will be good news for that camp, and if the arrangement is effected it will give it new life. Some of the mines over there show good prospects, and it is cheering to know that they may be yet worked for all they are worth. The water in the Grand Prize, since the abandonment of the hoisting works, has not risen above the 500 level. The labor of cleaning out this mine, which the Argenta joins, the latter being worked through the former on this account, will not be near so great as has been apprehended.

ARIZONA.

WATER AT DOS CABAZAS.—*Gold Note*, Feb. 11: The only objection that has heretofore been made to our mines, was that the water supply was so limited as to render it impossible to work them with profit. About a year ago a company of capitalists was formed at Denver, Colorado, their object being to develop several of the larger prospects along the immense gold ledge a mile or so north of Dos Cabazas. After a visit to this place, however, they decided at a meeting of the company, that "it would not be profitable to carry their plans into execution, owing to the apparent fact that a sufficient water supply could not be found near the mines for milling purposes." For this reason was a scheme abandoned that subsequent developments prove would have enriched the company. Many owners have relinquished designs of opening up and developing our mines because they deemed the water supply insufficient. Very few fortunes have been made without a considerable money outlay at the start, and experience has shown that it is not always safe to trust surface indications. If either of the companies that have visited this camp for the purpose of investment, had sunk a shaft in any of the properties, they would have discovered that water exists at a depth of 75 or 80 ft in inexhaustible quantities. When the Commonwealth Co. reached a depth of 120 ft on the Bear Cave mine, water flowed at the rate of 10,000 gallons per hour, and there is now standing in that mine at least 40 ft of water. Now that the water question has been definitely settled, it is hoped that parties in future will not permit opportunities which this camp offers to slip by them. At an expense of a few thousand dollars our mines can be opened so as to reveal to those engaged in the work millions of wealth.

SOMETHING NEW.—Dos Cabazas *Gold Note*, Feb. 11: An acquaintance just in from Wood Camp, informs us that while there he examined two valuable discoveries recently made in the eastern part of that district, named the H. Ordway and Nelson Hunt. The former is composed of a series of small veins of quartz, varying from 2 to 8 inches wide, lying but short distances from each other, and carrying an abundance of free gold—no silver. The latter is a vein of red silver ore about 18 inches wide, of high grade. Nothing of the kind has ever before been discovered in that part of the district; all of the ores heretofore found being free gold, galena and carbonate of lead and copper.

WINCHESTER DISTRICT.—*Gold Note*, Feb. 11: Dr. Stamhurn & C. A. Bartholamew, owners of the extensions north and south of the rich strike in Winchester district, were in town Wednesday, bringing in very rich samples of ore from one of these extensions, which is bonded for $30,000. The quartz was filled with chloride, brittle silver and free gold. They have refused $50,000 for the other extension. There are about 60 men at work on the original locations bought by P. W. Smith. A large amount of lumber is being hauled to the mine daily, for the use of the mine and out buildings—hoarding house, blacksmith shop, etc. A very rich strike of gold ore has been made about 12 miles from Winchester district.

FINE COPPER PROSPECT.—*Citizen*, Feb. 17: Chas. Odell called this morning with a fine specimen of copper ore taken from a mine called the Yellow Hammer, in the San Pedro district, which he and his co-owner, C. Carlton, are developing. The shaft is down about 30 ft and shows a vein 4 ft wide carrying considerable high-grade ore. The ore averages from 10 to 30% across the vein. This district is coming to the front.

GUNSIGHT.—*Star*, Feb. 17: The ledge of the Gunsight at a depth of 200 ft is found to be 52 ft wide. Near that point it comes in contact with the Silver Dirt vein, which is estimated to be 30 ft wide. The indications are that the two veins will come together as greater depth is reached. It is now estimated that there are $4,000,000 worth of ore in sight, more than enough to build the railroad between Tucson and Port Lobos. The monthly expenditure at the works is now $5,000, and this sum does not include purchases or freights. It costs considerable money to work a shaft 20 by 8 ft in width.

COLORADO.

DUMONT.—*Courier*, Feb. 17: The Unadilla Mining Co., of New York, has let a contract on the Surprise lode, the shaft being now about 40 ft deep. It is the purpose of the company to sink a further distance of 50 feet. Indications point to this property yielding ore of a high grade as the work progresses. So far the ore extracted has proved the character of it to be equal to any that has ever been encountered in this county.

IDAHO SPRINGS.—Meyers & Jenkins are running the Specie Payment stamp mill night and day on ore from the dump of the Crystal mine, which they make pay a fair profit. The new Miners concentrating mill will be completed some time next month.

ANOTHER STRIKE IN THE WIDE WEST.—Another valuable strike was made last Friday in the Wide West mine, on Leavenworth, in the Warren adit workings, towards the south part of the claim. This adit was started last summer and was driven on an ore vein a distance of 235 ft, which averaged in value 183 ounces of silver to the ton. From this adit a winze is being sunk which has followed a continuous ore vein worth 218 ounces. On last Friday this vein opened out to 3 ft of solid smelting ore, and since then in sinking nothing but ore has been removed from the winze. The other parts of the mine, Dr. Warren informs us, continue to look excellent. The last mill-run of nearly 15 tons, netted $4,103.00. The first-class ore milled 715 ounces per ton; the second-class, 287 ounces; the ore from the stope, 246 ounces, and from the Warren adit, 183 ounces.

PROMONTO STEADILY.—The reason why Clear Creek and Gilpin counties produce so steadily and largely is because the mines here are worked at a profit and we do not have to look to "booms" and foreign capital to keep things moving. Our ore market also has considerable to do with our prosperity. Ore as low in grade as 15 ounces of silver to the ton and 20% lead has a market value, while in districts not as accessible to smelting works it is often the case that ore three times as rich must lie on the dump and wait for time to give cheaper transportation rates and more reasonable smelting charges. The most important thing for those who desire to invest in mining property, however, is the fact that mining here has been reduced to a legitimate business; "booms" are a thing of the past, and consequently fancy prices as a general thing are not expected when property is offered for sale. It is safe to say that no other section of the country can offer greater inducements in this respect than old Clear Creek and Gilpin counties.

IDAHO.

ADA ELMORE.—Cor. Wood River *Times*, Feb. 15: On the 30th of last month a very important event in the history of this section of Idaho took place. I refer to the starting up of the new hoisting works of the Ada Elmore O. & S. M. Co. The mine and works are situated about a mile west of this place, on Bear creek. The Ada Elmore mine was among the very first locations made on Bear creek in 1863, and it has since passed through a great many hands before getting to its present owners, Mason & Co. of New York. Since True Rollins took hold of its management the company have expended in the neighborhood of $150,000. The works and mines are now under the superintendence of P. R. Roberts, a gentleman of 16 years experience in mining. Great credit is due both to Mr. Roberts and Mr. Rollins for the present fine working appearance and prosperous condition of the mine. Credit is also due to D. M. O'Sullivan, chief engineer, for the finished condition of the machinery, and the smooth manner in which it works. Also, to D. F. Potter, master carpenter, for the first-class workmanship displayed in the erection of the buildings. Also, to Abel Rowe and Samuel Gerrans, foreman of the mine and shaft, respectively, for the efficient work done under their direction. With the starting up of the new works, the Ada Elmore steps at once to the front rank of Idaho mines, and she will soon claim a leading position among the mines of the Pacific slope.

NEW MEXICO.

HELL CANYON.—*News and Press*, Feb. 16: Mines in Hell canyon, near Albuquerque, are promising. The Star mine, bonded for $50,000, yields $200 in gold to the ton.

DRY WASHER.—A. Bennett's dry amalgamator will not be operated in Golden under 3 months, although under contract to put one in by 15th.

SMELTER.—Las Vegas will have a smelter "in the near future." They claim to have leads near town that give from 29 to 44% copper.

SEVERAL stacks will be added to the Cerrillos smelter, and a roasting furnace for treating copper. There are now 2,500 tons of ore on hand. The Alaska mine in the Black Range has 900 ft of shafts. Three 8-hour shifts are sinking the main shaft, now down 200 ft, to a depth of 500.

TIN.—Tin has been found 9 miles south of Cranes on the A. & P. R. R. in Valencia county. The leads are at an altitude of 8,000 ft, and a district called New Cornwall has been laid out.

BLACK RANGE.—More miners are employed in the Black Range than ever before. Many sales are reported, and a number of mines have been bonded. Argentiferous gray copper was struck in the Eureka on Dry Creek.

SUCCESSFUL.—Shakespeare, Grant county, is happy, the new 30-ton smelter of the Shakespeare Con. M. Co., has started up. It is a success. The smelting ores of silver and copper will be a source of great wealth to the owners of property in that vicinity.

OREGON.

WATER.—Jacksonville *Times*, Feb. 17: The weather in the northern portion of the county seems to be much more moderate than here, and the miners all have plenty of water. Many miners are able to do some work during the day with the aid of reservoirs, but little effective mining has been done anywhere as yet. Capt. H. Kelly returned from Coyote creek this week, who informed us that the miners of that section are taking advantage of an excellent supply of water. H. F. Niday, of Lucky Queen Postoffice, was in town this week. He is engaged in working the Trullinger mine this winter, and says the prospects for a favorable run were never better. B. W. Huston, L. Orme, A. Koster and W. S. King, of Foots creek, were in town this week, from whom we learned that many of the miners of that section are at work, with the aid of reservoirs.

COLD.—The cold snap does not seem to have prevailed continually over the entire county, as Chappol & Co., Oin Lin and other miners along Applegate have been busily at work for some time past with a good supply of water. The cold spell is about over, and the miners will all soon be busily at work, as the ground, which is full of moisture, has thawed out and water is beginning to be plentiful. A favorable spring, with plenty of rain, is also anticipated, and the unusually large amount of snow in the mountains will prolong the mining season. The prospects for a good run are certainly not as gloomy as they might be. The Applegate Oravel Co. is piping, and expects to make a clean up soon. Some of the large hydraulic companies are now cleaning out their ditches. The Squaw Lake Ditch Co. is completing its reservoir and getting ready for active operations. Gin Lin will build a ditch several miles long to bring the water from Palmer creek to the red hills. Wm. Q. Brown, formerly of Althouse, is now in Douglas county on a prospecting tour in the interest of California capitalists.

UTAH.

CHRISTY.—Silver Reef *Miner*, Feb. 11: Recent developments in the California mine have uncovered a large body of high-grade ore on the 400 level north. This level is being advanced as rapidly as possible, and will be intersected by shaft No. 2, on the Maggie ground, which will be sunk an additional 500 ft for that purpose. As soon as this connection is made the two properties will be in admirable condition for handling the large ore bodies expected in each mine.

THE STORMONT CO.—So far during the present year this company has made an excellent record and the indications all point to a future of unequalled prosperity. The lower workings in the Buckeye continue in excellent ore; the stopes in the 4th level, both north and south, are yielding handsomely and have at no time showed to better advantage. The 3d level south is being pushed ahead into the Last Chance ground, and continues in 4 ft of good mill ore, and has now less than 50 ft to make to reach the localities—at some 200 ft greater depth—of the rich and extensive ore bodies that have made that mine so deservedly famous. The 3d level north will be extended 250 ft; a contract has just been let for the first 50 ft, and work has begun. This will make available a very large block of bonanza ground which has been proven by the second level directly above, for that distance. The ore reserves now in sight on both the 3d and 4th levels can be safely estimated sufficient for a 6 months' mill run. A uniform output of about 50 tons per day is maintained, which is raised partially through the Savage shaft.

THE BARBEE & WALKER.—Few mines anywhere can make a better showing than this reliable bullion producer, which sends its treasure forth to swell the commerce of the world with systematic regularity. A new shaft is being sunk on the ledge from the surface at a point 235 ft south from the main incline, which is now down 40 ft; the face is in a strong 4-ft ledge of $50 ore. This shaft will be driven to a connection with the 2d level south. The winze at the extreme north end of the 2d level north continues in good ore.

FROM COLD BASIN.—Messrs. Al. Grant and Don Liddle returned Wednesday from Gold Basin, and speak flatteringly of the mining possibilities of that district. They brought a large number of very handsome specimens of gold quartz, that we would recommend as a remedy for the pink eye. The Patterson 5-stamp mill is crushing an average of about 14 tons of rock per day, but not working the ore to a high per cent.

UTAH MINING.—Salt Lake *Tribune*, Feb. 15: There is very little excitement regarding mining in Utah, but the general result of the past year has been an advance, and the indications now are that the present progress is to increase with steadily swelling momentum. There is no reason why this should not be so. Utah has many advantages over all the country north and west. Supplies, labor, climate and transportation are all in Utah's favor, and when we think of the limited number of men engaged in mining, and consider what the yield has been and is, there is no reason to think that the mines of this Territory are not equal to those of any other region on earth. There are, so far, only two or three mines in the Territory which are really opened; the rest are merely surface scratchings. This, certainly, is not a fair showing, and we believe that mining men are taking the same view and are preparing to do more thorough mining than ever before. There is to be an increase in reduction works, and if present expectations are realized two or three districts which are mostly silent now will soon be making a noise. Then a new road is drawing near from the East, which will place some districts which are remote now, nearer Eastern markets than Salt Lake City itself is. With the coming of that road, conditions will change in many respects, and with its coming many a carload of ore or bullion will make its appearance from districts where only assessment work has so far been done. There will be a boom in mining in Utah by and by, and the time is nearer than many men new believe.

Centrifugal Cream Separation.

Some months ago we gave an engraving and description of a machine invented in Europe by Laval, for separating the cream from the milk by centrifugal motion. There were a number of these machines brought into use in England and on the continent, and one was set up in Massachusetts. The objection to the machine was its limited capacity and the very high rate of speed at which it had to be run—something like 5,000 to 6,000 revolutions per minute. At the English Dairy Show last fall there was a Danish machine shown in connection with the Laval, and exhibited a marked superiority over it. In fact, it seemed to possess a working capacity and feasibility of operation which seem to indicate that centrifugal separation may indeed be available for all dairies of large size. We hear that the Danish machine has already been introduced into Chile, and one of our large dairy managere is now in correspondence with the English manufacturers with the view of bringing one of the new machines to California.

In the consideration of the centrifugal cream separation the advantages of the new over the old system come in question. Of course there will be a great saving in that there will be no setting of milk and no arrangements therefor. The milk, as soon as drawn from the cow, is put through the centrifugal, and an hour or so after milking the dairyman has his cream collected and a stock of sweet, fresh skim-milk for stock feeding or other uses. All spoiling of milk by standing in hot weather is avoided and the whole process of butter making is so shortened that before a following milking the product of a foregoing one is put into commercial form and may be on its way to the market. There are many advantages in such a system of working, which will occur to the minds of all dairymen.

More than this it has been shown by most searching experiments in Europe, that more cream is to be had from the milk than by any of the old methods of separation. In an address before the American Agricultural Association, two weeks ago, Prof. X. A. Willard reviewed the recent investigations of M. Fjord, of Copenhagen, Denmark. M. Fjord commenced a series of experiments for the purpose of determining the relative merits of three different methods in obtaining cream and butter from equal quantities of milk of the same quality taken from one common sample, and the Danish government with commendable liberality appropriated several thousand dollars to the object. These experiments were continued through the entire year, a number of trials being made each month. The methods employed were the German centrifuge of Lafelt and an improved Danish centrifuge on the one hand, and the common shallow pan system of setting milk on the other hand. The milk was taken from a dairy of 200 cows, and after being thoroughly mixed, 600 lbs. were weighed for each experiment. This quantity was divided into three parts of 200 lbs. each; one part being treated with the centrifuge, one part set on the Swartz plan in ice water, and the third part of 200 lbs. being set shallow in common flat pans. The milk which was set in ice water was placed in pails having a capacity of 50 lbs. each, the milk having an average depth of 16 inches, and it remained in ice water for the space of 34 hours before skimming. The regular skimming time for the shallow pans was fixed at 34 hours after the milk had been set, though this was regulated somewhat by the condition of the milk from the end of May to the middle of September, when the milk was allowed to stand only from 22 to 30 hours before skimming.

Without going into all the details of M. Fjord's experiments, showing the careful manner in which they were conducted, the following table, he said, would show the peculiar vagaries of the milk in the yielding of butter by the three systems:

	Pounds of Milk for 1 lb. of Butter.		
1879.	Centrifuge.	Ice 34 Hours.	Shallow Pans.
May	27.6	30.0	30.4
June	25.4	28.3	28.8
July	26.8	28.0	30.5
August	28.5	27.7	31.7
September	26.6	27.6	30.9
October	24.3	28.7	27.9
November	24.6	31.5	28.4
December	24.2	28.5	27.4
1880.			
January	25.8	27.8	28.0
February	26.4	27.4	27.8
March	27.3	28.8	29.5
April	28.3	29.4	30.1

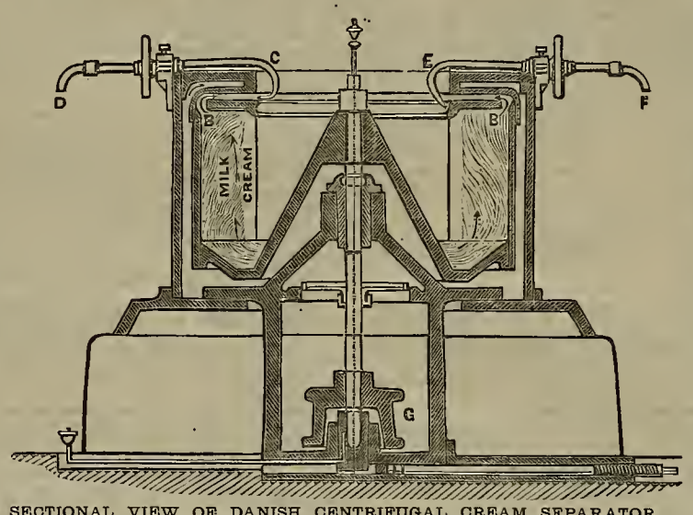
Referring to the figures in the preceding table it will be seen that the superiority of the centrifuge over both the ice and pan system, is especially noticeable during October, November and December, while during parts of July and August it falls below the ice method.

The ice method proves superior to the shallow pan during every month in the year, except in October, November, and part of December, its greatest superiority being in July and August. In October and November it falls below the pan system. The experiments were all checked by chemical analysis which exhibited a close argument with results obtained. The amount of fat left in 100 lbs. skimmed milk resulting from the centrifugal trials, was according to analysis, between 0.25-100 and 0.44-100 lbs. By the ice trials, the 100 lbs. skimmed milk yielded by analysis between 0.34-100 and 1.54-100 lbs., this last extreme being for November milk, when the smallest quantity of butter was obtained. By the shallow pan system the amount of fat in the skimmed milk ranged between 0.40-100 and 1.03-100 lbs.

The average for the year, or out of 12 simultaneous trials distributed over the whole year, was that the skimmed milk on an analysis yielded an amount of fat as follows: By centrifuge, 0.35-100 lbs.; ice method, 0.62-100 lbs.; and by shallow pans 0.68-100 lbs. The superiority of the ice over the pan system is not alone in yielding the greatest quantity of butter, but consists in its easier operation and more certain results in giving a first-class product.

Thus it appears that the shallow pan system which is so general in California is the least favorable to a large yield of butter of the three methods tested. And yet between shallow pans and setting in ice water, there is but Hobson's choice for California, for over the greater part of the State the ice method of milk setting is out of the question, unless artificial ice processes can be made much simpler and cheaper than at present. Possibly the centrifuge may come in to free us from the wasteful pan system and compensate us for the luxury (?) we lose in not having an ice crop to gather every winter. The drawback now is probably that centrifuges are expensive machines, which only rich dairymen with large herds can afford to use, but it is quite likely that a system which possesses such great advantages may be reduced to a cheaper basis so that a farm dairy may have its centrifugal as well as its churn.

In view of this device becoming useful here, we have reproduced a sectional engraving of the Danish machine from one of our English exchanges which will give our readers an idea of its manner of operation. The percentage of cream to be removed can be regulated with the greatest exactness, and this separator runs at only 2,000 revolutions per minute. The whole milk is run into the separator from a tank or



SECTIONAL VIEW OF DANISH CENTRIFUGAL CREAM SEPARATOR.

container. The skimmed milk escapes at B, and is drawn off by the beak and tube, C and D. The cream, when gathered in sufficient thickness, is drawn off by the beak, E, and tube, F. If thin cream be required, the cream is drawn off continuously, but if thick cream is required, the beak, E, is put into work when desired; that is to say, when the wall of cream is seen to be of sufficient thickness. In this power over the quality of the cream consists one of the most valuable points in this machine. The working of the machine is admirable. Looking into the top of the whirling cylinder, the milk and cream are seen standing up in two distinct white walls around the vessel, and a couple of brass tubes dipping in run off the two products as they collect inside.

A Comstock Ruby.—Very little search has ever been made in this State for precious stones of any kind. The fact that a very fine ruby, which weighed about one carat when cut, was found at Cedar Hill at the time they were mining there by hydraulic process will probably be news to most of our people, yet such is the fact. The stone, in the rough, was bought by John Rothenbucher, a jeweler, still in the city, who sent it to New York, and had it cut. It was of a fine claret color and of the first water. Mr. Rothenhucher informs us that some very fine rubies are found in Idaho. He now has in his possession some of them in the rough, just as he bought them. Rubies are next in value to diamonds.—*Virginia Enterprise.*

How Drift Mining Doesn't Pay.—A few days ago the Derbec Blue Gravel Mining Co. shipped to the bay bullion to the amount of $9,500. This is a drift mine and is worked in the same manner that the Sacramento *Bee* and Marysville *Appeal* would like to have the Excelsior, Blue Tent, North Bloomfield, Milton, Eureka Lake and other hydraulic mines. The point of this reference becomes apparent when it is known that last month the expenses of the Derbec were $11,000, leaving the stockholders to pungle up an Irish dividend of $1,500. Drift mining pays—to leave alone.—*Nevada Transcript.*

Gold in Australia.

There appears to be a genuine revival of interest in the Australian gold fields and an increase of expectations therefrom, which cannot fail to be welcome in the present position of what may now be called the gold question. The Melbourne *Argus* says that the various gold fields of Victoria continue to attract much attention, and a large amount of Melbourne and other capital is being invested in prospecting in almost all directions over the auriferous districts. Several of the well-known extensive quartz mines of Sandhurst have recently yielded such rich stone that a considerable rise in the prices of the shares of a large number of Sandhurst mines has resulted. The industry is also said to be steadily improving in the Beechworth district, and some of the reefs lately discovered there are giving very satisfactory results. Increased attention is likewise being given to the Wedderburn district. The large yields obtained for some time past from the deep alluvial mines at Kingston and in the Smeaton district are being kept up, but the usual difficulties which spring up where gold has to be obtained by sluicing and washing operations are affecting these and other large mines in the colony. An injunction has been obtained by a Mr. M'Kenzie, a land-owner, against the Madame Berry Co., to prevent the latter from spoiling the water of a stream which runs through his land by sluicing from the mine. The effect of this injunction is to prevent the company from working the mine, and a large number of men have been thrown out of employment in consequence; and it is feared that if other land-owners take the same course of action gold mining may be stopped in the colony altogether. The Madame Berry Co. have issued a writ against Mr. M'Kenzie claiming damages to the extent of £20,000 for the latter having "unnecessarily forced down the value of the company's stock in the market, when a more simple remedy, in which the company might, and, as is alleged, would have readily acquiesced was open to him." The Government meanwhile have introduced a bill "to give mining companies power to enter upon either Crown or private lands to make dams and reservoirs in which sluice may be collected instead of being run down water courses, compensation, of course, being paid for any injury done to the lands by the making of the dams or reservoirs." The hill is also intended to prohibit mining companies from running sluice into rivers or creeks at all; but this provision is strongly opposed by members of the Victorian Parliament representing mining districts, on the ground that it will stop mining. It has since been stated that a compromise between the Madame Berry and other companies and the land-owners concerned has been effected. The New South Wales mines are also said to be constantly showing new signs of richness.—*London Mining Journal.*

The latest news from Ivanpah, says the San Bernardino *Index*, is that the mines there are being worked with very good results. The last strike in the Alley mine was a very good one. Several tons have been taken out that work $2,000 to the ton. They are now taking out a lot of ore from the old works that was not considered worth doing anything with when it had to be shipped away to be worked, but it can be worked now to very good advantage, as it is easily got out. About a hundred tons of it can be taken out at little cost, and it works $175 per ton.

A Novel Way of Making Ice.—Some Norwegians who settled in Quigley's gulch, about a mile from Hailey, last summer, have been making ice in a novel way. They got a lot of coal-oil cans which they filled with water from the creek, and left them outside during the night. In the morning they would punch a hole through the ice, let out the water, and thus get hollow blocks. They have a log house, 20x40 ft., filled up with ice made in this way, and are still at it.—*Wood River Miner.*

Central America.

A Miners' Paradise Found in Honduras.

Under date of January 25th, John S. Jones gives the Chicago *Mining Review* a long account of a trip he recently made to Honduras. He landed in Truxillo, a city over 300 years old, founded by Cortez. Mr. Jones then proceeds to say:

On presenting my credentials to the chief magistrate I was at once introduced to the chief officials, and, on making known my business, I was allowed to pass all my supplies and tools free of duty, which was quite a great favor, as the usual duties are almost prohibitory—pork is charged about $15 per barrel, and flour $3 per barrel. As soon as we procured mules we left for the interior, and, after five days' travel over a beautiful and romantic country, reached Olanchito, distance 100 miles, in the Department of Yoro, located in the valley of Olanchito, on the river Ajuan, a stream carrying 5,000 miners' inches of water in the dry season. About 40 miles from Truxillo we found undergrowth and brush almost impenetrable if you left the trail. Mahogany, cedar and a variety of other timber is very abundant in the valleys. The soil is a black loam, extremely rich. The balance of the route was through open, beautiful valleys, with abundant clear, cool streams of rapid-running water. The foothills are lined with pine timber. The route thence to Arnal is level and rich in verdure. At this point we reach the mountains proper at an elevation of about 2,500 ft. Here are found rich gold veins in quartzite formation. Timber and water are here in abundance. The next point of interest was Ocon, a town of about 1,000 inhabitants, located in a valley surrounded by mountains, which contain, without doubt, immense mineral wealth. From this point over the mountains to Manquallio is a distance of 40 miles. The inhabitants here are somewhat more thrifty in their habits. In this place gold is found in quartz, and also in the gravel deposits. We then proceeded to Yocon, about 18 miles, having crossed the river Manquallio 22 times. This city contains about 2,000 people. I found a rich vein of copper near the city. We then went to Juatalapa, the capital of the Department of Olanchito, containing 5,000 inhabitants. Here I had the honor of meeting Governor Don Santiago Mesa, also Don Floilan Turewe and ex-Governor Jose M. Aguerre, to all of whom I feel under lasting obligations for the many courtesies extended to me in that far-off land, and from whom I gained much valuable information. This city is located on the Guyape river, which is one of the most important rivers in Honduras, navigable to within a short distance of the city for light draft boats. The mountains surrounding this place show great indications of mineral wealth, and the gravel deposits above and below are, without doubt, the richest placer diggings now lying dormant, and, by a system of hydraulics, could be made the most profitable mining enterprise that ever was known to man. The climate in this locality is most beautiful, being at an elevation of from 3 000 to 4,000 ft. above the sea. It is very healthy, and most advantageous to those of weak lungs, as it is never colder than 50° nor warmer than 90°. The rainy season commences in September and extends into the middle of November. This is the least desirable season. The inhabitants of Honduras extend an open hand to all Americans, and seem anxious to adopt American ideas. The President is elected every four years. United States laws are followed closely. Tegucigalpa is the capital of Honduras—population $15,000. The present Executive is Marcus A. Soto, a progressive, go-ahead man, who does all in his power to encourage the natives in making improvements. A telegraph line is now in operation from the coast to the capital. The natives are very docile and peaceable, and seem to be anxious to have Americans settle in their country, and treat them always with great hospitality. The placer beds are immense, and when machinery is placed on them the production will be incalculable. A grand opening is offered to young men of energy and business ability, requiring but little money to make a large fortune. I propose returning to Honduras in a few weeks.

Dolores Mining District.—Among the many rich and favored parts of the State of Chihuahua—where now American prospectors, backed by American money, are seeking to uncover the hidden mineral wealth, and where all sources for gold and silver are being made more valuable by increased production under improved appliances—one district is coming prominently to the front. Within the past few months quite a number of our enterprising citizens have become interested in mines of this fabulously rich section. A stamp mill, of small capacity, however, was shipped to Tomasichie by a company formed here. This event drew considerable attention to the mines of that locality. Dolores district, though distant from Chihushua City, the mining center of the State, includes a country of wonderful resources, not only of a mineral nature, but timber land, grazing ranges, as well as an abundance of water. —*Link.*

The Central mining company paid a dividend of $2.50 per share in New York on the 4th. This is the 20th dividend, and the total is $1,010,000. The mine is a copper claim in Michigan.

Barely Prospected.

The part of Southwestern Nevada which is compriced in the counties of Esmeralda and Nye and that part of Southeastern California of which the counties of Mono, Inyo and San Bernardino are a part, has been, within a few years, a region of country comparatively but little known. The hardy prospector, of course, had run over the entire region more than 20 years ago; but with the exception of at a few points, widely separated, he made no discoveries worthy of note or from whence resulted anything to bring into prominence the mineral wealth of that particular part of the Pacific Coast. Of course, Aurora was an exception 20 years ago, and for three or four years its fame spread. But oblivion came, and until the resuscitation of Bodie no attention was paid by the masses to this entire country. During the past four years, however, startling changes have taken place,—but startling only in a small degree compared with the changes the next four years will bring. This entire region spoken of has been difficult of access and costly to penetrate. The most sturdy prospector had his nerve and muscle severely tired during his endeavors to expose some of the wealth in its mountains. This state of affairs is gradually changing, and one of the most potent factors in causing this change is the railroad system now traversing this part of the country. This railroad system is yet only in its infancy, the Carson and Colorado being the advance guard and pioneer. When it will have penetrated another 150 miles further into the wilderness the scope of country which will be thrown open to the prospector and miner will simply be illimitable in extent and mineral value. The pioneer prospector has already proven that in all these mountains and valleys are contained minerals of all kinds and descriptions. With railroad facilities these early discoveries will be again brought into prominence and developed; new ones will be made, and a country that is now barely supporting a few hundred people will increase in population and progress until the output of its gold and silver bullion, its borax, soda, salt, coal, mica, nickel, lead and other valuable treasures of nature—which are here in abundance awaiting development—will be so great that the attention of not only this immediate people, but also the attention of those distant from here will be called to the mineral resources of this part of Nevada and California. The daily increasing facilities for exploring the country will also be shortly felt, and from Walker lake on the north to the dried plains of San Bernardino on the south, and from Grantsville on the east to Fresno flats on the west, the mountains will swarm with prospectors before 12 months. In a comparatively unprospected region this state of affairs will certainly produce some good results, and the discoveries that are liable to be made will materially assist in the development of a now almost unknown country.—*Candelaria True Fissure.*

Sweetwater District.

A correspondent of the Esmeralda *Herald* of the 4th instant, says: I am pleased to give you the progress and status of the Sweetwater Mining District at this date.

The Summers mine is working a full force of men night and day, with Mr. Matt. Young as foreman of the mine. The ore is improving in quantity and quality, which the developments have shown in the last ten days, and the ore that is now exposed is better than was ever shown in the mine. There are 350 tons of first-class ore at the mill, which is situated two miles east of the mine. The mill is running at full capacity—five stamps, one pan and one settler. The mill is under the supervision of Mr. James Laraway, assisted by Mr. A. Soderling, of Bodie. They report the ore working up to 85 and 90 per cent. The mill has only been running at its full capacity a few days. On January 30th they made one retort of 45 lbs., and January 31st one of 55, crude bullion, and to-day will make the first bar of bullion of about 1,000 ounces, which I think will be about 900 fine. The value of the bar will be $1,200. When everything is in good order they will ship more silver bullion from their 5-stamp mill than any other 5-stamp mill in the country. The town of Pattersonville, which is situated near the mill, is improving very rapidly, many new buildings being in course of construction.

Mill Runs.—The unreliability of specimen assays to demonstrate the value of a mine, has received such general and merited denunciation at the hands of the mining press, that people have of late placed but little confidence in reports of high assays. The latest dodge now is to expatiate on high results given by mill runs, as having a tendency better to deceive. We notice in the daily exchanges reports of mill runs on various properties giving results all the way from 100 to 10,000 ounces, from properties that have not a pound of pay ore, and many of them have never mined a ton from their entire workings. The way this is done, the parties developing save every particle of high grade ore material for months, and perhaps after accumulating a sack or two out of 100 ft. of working that has cost not less than $1,000, they take their sample to the mill, have it run through and get the assay of the same, and then endeavor to gull the credulous with sensational reports of a big mill run.—*Kokomo Times.*

Useful Information.

Solid Petroleum.

The conversion of Petroleum into a solid and safe substance for transportation seems to be attracting considerable attention in foreign countries where no pipe lines exist. A St. Petersburg paper says: How shall we transport petroleum? is to-day the most important question for all branches of the naphtha industry, and no less so for the consumers who live at a distance from the wells. All the methods of transporting petroleum hitherto in use, whether in wooden or paper barrels, in iron pipes, or iron caissons that are placed on ships or cars, possess disadvantages which are sufficiently well known, especially as regards leakage and evaporation, and also the great danger from fire.

These misfortunes which afflict so severely both dealers and consumers and increase the cost of an article of such importance in domestic economy, have been banished at a single stroke by the discovery of a German named Dittmar, who has succeeded in converting liquid petroleum into a solid substance. As early as 1872 the idea arose in America of solidifying petroleum so as to put it into a more suitable form for transportation, and in that year no less than 12 patents were taken out for this object without any single one of them being found practical. What a range such a discovery would cover, as would change petroleum into a solid wax-like body, can scarcely be conceived of, especially for the Caucasian naphtha industry, where there is a lack of suitable wood for making the barrels, which has a very serious effect upon the industry.

The Moscow *Zeitung* also contains a thorough discussion of the new invention. The journal says: Solid petroleum has not yet come into market because the patents have not yet been issued, but a company has been formed in Russia for carrying out the invention. By the process adopted by this company it is claimed that a quantity of petroleum, which would involve an expense of $36 to put it into proper cases for transportation, including the loss of leakage which would naturally ensue, might be rendered solid at a cost of only $4.

But to this and other remarks that have appeared in the technical journals the Russian *Pharmaceutical Zeitschrift* adds the following: It is found that petroleum when heated will take up a certain quantity of dry soap, and that the solution on cooling will form a jelly, which, when ignited, drops off in pieces that soon go out like burning sealing wax. Dilute acids, like acetic acid, restore the fluid condition (evidently owing to a decomposition of the soap). In this way is explained all that has been asserted and claimed for the solid petroleum.

Only 1½% of soap is required to form a gelatinous mass like opodeldoc, but with 3% of soap it is much more firm. In this operation there separates a small quantity of liquid products that do not become solid, and which probably consist of the lower boiling constituents of petroleum. The presence of these in the solid mass, is, of course, dangerous, and still more so because it always has to be liquefied before it is used. The contents of the wooden boxes used in transportation, will soon ooze through the wood and becoming mixed with air will give off explosive vapors. On this account the author comes to the conclusion that the advantages of solid petroleum are entirely imaginary, as being a tedious, troublesome, expensive and dangerous operation.

What is an Apple?

Is an apple a fruit? It is generally regarded so; but, botanically speaking, a *fruit* is that part of a plant which contains the seed, and it is nothing else. The *core* of an apple, then, according to this, is the true fruit, for that is the part that contains the pips, and the pips are the seeds. It is a cartilaginous five-lobed capsule, splitting along the edges. "What oddities," says Dr. M. T. Masters, "these botanists are; they leave on their plates the fruit, and they eat something which they say is not the fruit! What is that something which is not the fruit? To answer this question to his own satisfaction, the reader should see before him a flower of an apple or pear in the earliest stage of its growth, and he should trace in other stages, from this earliest condition to the ripe state, the growth of the apple or the pear."

"A careful examination of this kind," says our author, will "enable him to discover that the flesh of the apple or pear is nothing whatever but the end of the flower stalk, which gradually swells out into a succulent mass, and which holds embedded within it the true fruit—the core. What in ordinary language is called the fruit is, then, only the swollen flower-stalk. Alechemillas and spiræas, peaches and cherries, are not to be had in flower just now, else a cut down through the center of the flower of either of these would reveal the cup-like stalk encircling the young fruit in the center, just as a pill is inclosed within a pill box. Now, suppose the cup to be fleshy, and so thick as to come in contact with the fruit, and we have exactly the condition of an apple. So, then, to say that the core of an apple is the true fruit, and the flesh thereof the dilated flower stalk, is no dogma to be accepted as an article of faith, but it is a statement which anyone with a pair of eyes, ordinarily nimble fingers, and a little patience, can, at the proper season, verify for himself. To be able to recognize the core of an apple as the fruit proper, and to see in the flesh of the apple a swollen flower stalk, is not to indulge in a mere botanical technicality, as some might at first be inclined to suppose, but it affords a means of ascertaining a truth, and, as such, of opening up possibilities of future utility and development; for truth is never barren of result—the sterility lies with the man who does not avail himself of the truth so far as he can. Deep thoughts to be evolved from the castaway cors of an apple!"

How to Make Peppermint Drops.

Take a convenient quantity of dry granulated sugar; place it in a pan having a lip from which the contents may be poured or dropped; add a very little water, just enough to make the sugar a stiff paste, two ounces of water to a pound of sugar being about the right proportion; set it over the fire and allow it to nearly boil, keeping it continually stirred; it must not actually come to a full boil, but must be removed from the fire just as the bubbles denoting the boiling point is reached begin to rise. Allow the sirup to cool a little, stirring all the time; add strong essence of peppermint to suit the taste, and drop on tins, or sheets of smooth white paper. The dropping is performed by tilting the vessel slightly, so that the contents will slowly run out, and with a small piece of stiff wire the drops may be stroked off on the tins or paper. They should then be kept in a warm place for a few hours to dry. If desired, a little red coloring may be added just previous to dropping, or a portion may be dropped in a plain white form, and the remainder colored.

There is no reason why peppermint should alone be used with this form of candy, but confectioners usually confine themselves to this flavor. Any flavor may be added, and a great variety of palatable sweets made in the same manner. If desired, these drops may be acidulated by the use of a little tartaric acid and flavored with lemon, pineapple, or banana. In the season of fruits, delicious drops may be made by substituting the juice of fresh fruits, as strawberry, raspberry, etc., for the water, and otherwise proceeding as directed.—*Confectioner and Baker.*

Solidifying Wines.—An Italian has invented a process for solidifying wine. From a small quantity of this extract may be obtained a bottle of generous wine of good taste and beautiful color. The object is to victual ships and supply armies. A chemist in Marseilles has found a combination by which he can solidify and even crystallize brandy. The brandy in its new form looks like alum. It entirely loses its smell. The facility with which it can be transported is of course the main recommendation of the new invention. An Oregon inventor, some six years ago, took out a patent for solidifying cider, which appeared to work very well. It was solidified by being thrown in a spray upon a heated revolving cylinder, from which it was afterwards cut as a sheet of solid cider. Some specimens were exhibited at the Centennial Exhibition at Philadelphia, in 1876, and attracted much attention.

Good Health.

An Anti-Malarial Plant.—In lectures on medicine by Dr. Thomas Watson, delivered in 1847, speaking of malaria, he says: Dr. St. Cartwright, of Natchez, asserts that the *Jussieua grandiflora*, or floating plant of the bayous and lakes of lower Louisiana, has the power of preventing the development of malaria in regions particularly adapted to its generation. He affirms that it purifies all stagnant water in which it grows; that the lakes and bayous inhabited by it, being as pure to sight, taste and smell as if it had just fallen from the clouds. He ascribes to the presence and peculiar hygienic or health-preserving properties of this plant the remarkable exemption of the inhabitants of lower Louisiana from malarious or miasmatic diseases. The fact, he remarks, that the region of country in which this aquatic plant abounds is exceedingly healthy, can be established beyond cavil or doubt. It nevertheless contains more stagnant water and swamps than any other part of the United States. One of our readers asks us what is now known concerning this plant, which was put forth as a malaria-killer in 1847, and whether the observation given above is substantiated by facts. The best we can do is to appeal to those acquainted with the botany and health of Louisiana to inform us. If there be such a sovereign remedy for malarial country, it should be generally known. Who will tell us about the *Jussieua grandiflora?*

Put it on at Once.—A loose red woolen flannel shirt should be worn next to the skin, both summer and winter. It must be "loose," so that its moving upon the skin may keep up a good circulation there; "red," because white flannel fills up, becomes stiff and impervious; "woolen," because woolen flannel conveys the perspiration from the under to its outer surface, where either the cotton shirt absorbs or the air dries it without injury to the body. On account of these properties, sailors wear woolen flannel even during midsummer in hot countries. Of course, a very thin material should be worn in summer.

Nature of the Diphtheritic Contagium.

In the spring of 1880, Drs. H. C. Wood and H. F. Formad, under the auspices of the National Board of Health, began a series of experiments upon rabbits with a view of determining the nature of the contagium of diphtheria. The animals were inoculated with diphtheritic membrane taken from the throats of human patients.

In the course of these researches, it was determined that there is nothing specific in the production of false membrane in the trachea, and that traumatic pseudo-membrane accurately resembles the diphtheritic, except that micrococci are not quite so abundant in it. The experimenters conclude that the disease produced by the diphtheritic inoculation was really rabbit diphtheria, because the poison giving rise to it, the symptoms during life, and the *post-mortem* lesions were identical. In addition to this, the contagiousness of the disease was retained. They accept the experiments of Curtis and Satterthwaite, showing that the infectious character of diphtheria depends upon the solid particles of the membrane; furthermore, their researches lend them to conclude that the micrococci are in close relation with the essential poison of diphtheria, being either the virus itself or the producers of it. The results of culture of these bacteria lead them also to assert that there is no difference between the micrococci of simple sore throat and those of diphtheria, except in activity of reproduction; the two are the same organism, existing under different conditions.

Drs. Wood and Formad believe that the vitality under artificial culture is in direct proportion to the malignancy of the case from which the plant is taken. They have succeeded in producing diphtheria by the inoculation of cultured micrococci, but never with those of a generation later than the second.

M. Pasteur has indicated that an inert organism may become virulent, and *vice versa*, and in the same way they believe themselves able to prove that the micrococci of the mouth are really identical in species with those of diphtheria. That oxygen may be potent in converting a virulent into a non-virulent organism, they regard as probable, from the effects of exposure of dry membrane. The micrococci of a catarrhal angina or trachitis may, under favorable circumstances, be transformed into micrococci of diphtheria, and a self-generated diphtheria (*i. e.*, endemic) ensue; or external conditions may favor the transformation of inactive into active organisms, and these may lodge in the trachea and also cause diphtheria (*i. e.*, epidemic). In the first instance, the disease may spread by organisms exhaled by the breath. Diphtheria will vary in contagiousness according to the development of the virus—malignant diphtheria will be more contagious than the mild endemic form. The conditions outside of the body which favor the transformation of inactive into active micrococci, and agents destroying these organisms, remain yet to be studied.—*Phila. Med. Times.*

A Skin Tinged with Yellow, that is, abnormally so, is the outward and visible sign of a lack of regularity in the performance of the bile-secreting function, and that the biliary fluid has strayed from its proper channels, impeding digestion, disordering the bowels, and producing aggravating internal disorder. No time should be lost, under such circumstances, in resorting to the standard anti-bilious remedy, Hostetter's Stomach Bitters, the good effects of which are in nothing more conspicuously shown than in its reformatory action upon the great bile-secreting organ. Renewed activity, when the liver is sluggish, a regular action of the bowels, the disappearance of sick headaches, heartburn, flatulence, and pain in the region of the organ principally disturbed, may be anticipated with just confidence by any bilious subject who begins with a course of this peerless regulator, and debilitated or nervous sufferers experience the greatest benefit from its tonic influence, while its efficacy in rheumatism and kidney weaknesses is equally well authenticated.

Deaths from Singular Causes.—Two distinguished men have just died in Paris from a singular cause. Col. Adan, Director of the Institute Cartographique, thought he had a chair behind him, and in sitting down fell with all his weight on the floor. He died within a short time from the effects of the accident. About 10 days before M. Pirson, Governor of the Banque Nationale, went to a dinner party at the Spanish Legation, and sat beside the hostess. She rose from the table, and then, continuing a conversation, resumed her seat. M. Pirson followed her example, but a footman had meanwhile removed his chair, and in his fall he injured his spine and survived only a few days.

Hygiene of Beds.—Beds should be made of such material as will absorb as little as possible of dampness or impurities of any sort. One of the most important means of keeping a bed in a wholesome condition is thorough airing every morning. Immediately after rising, the occupant should throw open the bed and the windows of the room, thus securing a thorough removal of the foul emanations from the body which accumulate during sleep. When this is not done, the foul products accumulate, and the bed may become a source of disease.

SAN FRANCISCO:

Saturday Morning, Feb. 25, 1882.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—New Ore Smelting Furnace; Hydraulic Mine Draining Apparatus; Academy of Sciences, 121. Passing Events; Wire Mine Models; Prospects for the Coming Season; Ditches and Canals; Quicksilver Production in Spain; Quartz Mining in the Vicinity of Auburn, 128. Notes on Mica; A New Gentian, 129.

ILLUSTRATIONS.—Smelting Furnace for Fine Ores; Hydraulic Water Lifting Apparatus for Mines, 121. A New Gentian, 129.

CORRESPONDENCE.—Inyo County Mines, 122.

MECHANICAL PROGRESS.—The Blacksmith's Forge; New Departure in Finish of Railroad Cars; Car Construction; Tests of the Quality of Steel, 123.

SCIENTIFIC PROGRESS.—Advance in Photography; Fertilizer Experiments; Effect of Electric Lighting on the Demand for Gas; Oxygen as a Source of Energy; Electrical Ball Finding; A Fog-Bow Before Sunrise; Wet and Dry Thunderstorms, 123.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Assessments, Meetings and Dividends, 124.

MINING SUMMARY from the various counties of California, Nevada, Arizona, Colorado, Idaho, New Mexico, Oregon and Utah, 108-9.

USEFUL INFORMATION.—Solid Petroleum; What is an Apple? How to Make Peppermint Drops; Solidifying Wines, 127.

GOOD HEALTH.—An Anti-Malarial Plant; Put it on at Once; Nature of the Diptheritic Contagium; A Skin Tinged with Yellow; Deaths from Singular Causes; Hygiene of Beds, 127.

MISCELLANEOUS.—The Pirn Mining District; Our Quartz Mining Industry; Copper for Old Iron; The Mines on Military Hill, 122. Centrifugul Cream Separation; Gold in Australia; Central America, 126. Barely Prospected; Sweetwater District, 127.

Business Announcements.

Wanted—Mining Manager for Quartz Gold Mine.

Passing Events.

As we have stated in another column, the prospects of the coming season have become assured as favorable, owing to the abundant snow-fall in the mountains, much to the pleasure of the miners. It will not now be long before the unfortunate litigation concerning the hydraulic mines will be settled, when, it is to be hoped, all will go smoothly again.

Up on the Comstock, the quartz mining center of the coast, the shutting down of work on the Forman shaft is not encouraging. The works have been shut down pending the settlement of financial matters with the Belcher and Crown Point, which companies are partners in the shaft, and who are behind in their payments toward the cost of sinking. It was the intention of the Crown Point and Belcher companies to clear out the drift connecting with the Yellow Jacket, on the 282S level, and work through that, but owing to the water troubles at the Jacket this cannot now be done.

Washington's birthday, which occurred this week, was quietly celebrated in the city. In the country there is far more of the holiday feeling prevailing than seemed possible a short time ago. The rains have been general and though not generous have cheered all by their present effects and by the promise of more as growth requires it. There is reason to expect a very good year throughout the State, and an aggregate of produce which will be creditable. Here and there a district will probably but hold its own and require courage to wait for another more productive season, but the general outcome of 1882 will be better than has been hoped for during the earlier portion of the winter.

Wire Mine Models.

The French mining engineers have a system of presenting a relief, and, at one view, the form and features of the surface and the subterranean works of the mines at their proper relative depths beneath the surface.

The method consists in producing the form of the surface in equidistant contour lines represented by wires of sufficient strength, the contours being taken in regular intervals of vertical distance, and the horizontal wires being held in their relative position by other wires joining them transversely in such a manner as to form a design presenting the relief of the surface.

To make a model of this sort a map of the surface is first prepared, on which the contour lines are carefully drawn. Each of these contours is then reproduced in brass wire. In order to place these contours in their proper relative position, a series of profiles on wood is employed, formed of thin boards set up vertically and parallel to each other, each cut on its upper edge so as to form the profile of that part of the surface of which it represents a section. The contour curves in use are placed upon and supported by the system of profiles; and after being adjusted precisely to their proper relative position, are joined together by other smaller wires, so placed as to bind the network firmly, and at the same time to represent other features of the surface, such as the crests of the ridges, the beds of the ravines, the boundaries of the properties, the lines of the roads, the courses of the streams, etc.

Upon this network it is then easy to place the representation on the desired scale, of the principal buildings on the surface, removing finally the wooden profiles from underneath, and substituting for that means of support a sufficient quantity of small uprights of the desired length, and at convenient points.

The underground works of the mines may be shown in similar manner. The various drifts, tunnels, and cross-cuts are represented by horizontal wires, each having the form required to correspond to the course and length of the work represented by it.

The horizontal wires being placed in proper relative position beneath the surface net, are connected with other wires corresponding to the shafts, inclines, winzes, etc., and other accessory works of the mine, the whole being also supported from below by uprights placed at convenient points.

At the same time, the surface wires and those of the underground works can be made to show the main features of the geological formation by coloring them with different tints indicating the various rocks exposed on the surface or traversed by the mining works below ground. The form of the surface, its nature expressed by color, and the relative position of all the objects shown upon it, are brought out in bold relief, while the spaces between the wires afford a clear view of all the works lying beneath.

At the time of the last Paris exposition, a French mining company exhibited a plan of this sort, the subject of which comprised a superficial area of about three miles long by two miles wide, beneath which were represented a portion of the underground work of the collieries and iron mines belonging to the company.

This plan seems better than the plaster or models. Some excellently-made glass mine models, by the way, are shown at our State Mining Bureau. From the description we have given, anyone of ordinary skill can construct a wire mine model.

Prospects for the Coming Season.

The abundant fall of snow of the past few weeks has been most welcome to the miners of this State. Throughout the mining regions, the mountain tops and the canyons are covered and filled with snow, insuring an abundant supply of water for the coming season. Of course, in many places this has stopped work and stopped prospecting, but both will be prosecuted again with renewed vigor at the first opportunity. Altogether, the prospects for a good year of mining are very favorable, and the miners feel encouraged to stick to their claims. As an index of what the feeling is in this respect, we take the following from the Greenville (Plumas Co.) *Bulletin* of last week: "For weeks past the town has been quite dull, but already a change is seen. The certainty of having plenty of water has dispelled the gloom, and already evidences of active preparations for energetic work are evident. The success of prospectors in the fall has excited a good deal of interest; so much so, that some mechanics talk of giving up their regular occupation as soon as spring opens, and going after quartz. Some transactions that have been made lately in connection with some of the mines in the neighborhood have given warrant to the belief that the coming season will witness an unusually vigorous display of mining in the district. Nothing is now needed but a few days of warm weather, or a little rain, to set the snow melting, and all the mills in the neighborhood will be running."

IT is said that the expense of running the largest size furnaces at the Richmond works, including the price of extracting the ores, charcoal, wood, labor, hauling, and other incidentals, is $1,000 per day.

Ditches and Canals.

A Calaveras County Work.

For conveying water to the mines a ditch system of very great magnitude has grown up in this State, and millions of dollars are invested in this class of property. Few people who have not examined the subject are aware of the engineering difficulties overcome in building these ditches, or of the expense entailed in carrying on the work. All along the lines of the ditches small villages and camps spring up, where live the families of the men who are engaged in the mines. Without these ditches the mines themselves, in most cases, would be of little or no value, since it is upon the water they depend to be worked. In fact, were it not for these ditches a good many parts of the State would hardly be settled up. The storage reservoirs, forming part of the system, keep back the water from the melting snows for utilization during the dry season. Thus the mines can be worked during months when there would otherwise be no water. Concerning the building of one of these ditches the following information is forwarded to us from J. S. M., at Copperopolis:

I had the curiosity recently to visit the canal built by Mr. L. J. Lewis on the banks of the Stanislaus river, Calaveras county, and was surprised to find so large an operation progressing and so little stir made about it. A 12-horse power boiler was set on wheels, a movable track in two sections was laid, and the boiler run down the canal as it was built; the steam made was used to run a No. 3 Ingersoll drill, which, with quantities of Excelsior and Giant powder, made the hills reverberate and shake to their foundations. About 50 men have been employed several months in blasting out great ledges of metamorphic and other slate rock to the depth of 12 or 13 ft., averaging 9 to 10 ft. wide, besides cutting through cement sand about the same depth and width for a long distance.

At the head of the canal a flume 8 ft. high and 15 ft. wide is built of two-inch plank, with base timbers 12 inches square, strongly bolted deep into the bedrock with one-inch iron bolts, and the whole encased to the top by a stone wall six ft. thick. At the head of the flume are four gates for the ingress of water. From the flume to the first high reef of rocks there is a double (chambered) wall 660 ft. long, 10 ft. thick on the bottom and 6 ft. thick on the top, strongly tied at intervals with heavy rocks, and the chambers filled by running loam into them with a small head of water, making the wall as solid as the hills. In this manner the wall has been built along the line of the canal, presenting a formidable appearance and proof against flood and storm. The object of the canal is to take all the water from the Stanislaus river eight or nine months in the year, that the river bed may be cleared of its gold and that the bare may be worked; also to furnish water power for mills that are to be erected to work the great bodies of quartz in the mines contiguous to the canal, and which will furnish 500-horse power when finished, one and one-half miles from the head. This is the largest canal in this part of California, and reflects great credit upon the builder and the capitalist interested in the operation.

Quicksilver Production in Spain.

Through the kind attention of his correspondent at Almaden, Spain, Mr. J. B. Randol, general manager of the New Almaden mines, Santa Clara county, is enabled to place at our disposal the accompanying statement of the production of quicksilver at the famous Almaden mine for the year 1881.

As usual there was no work in June, July, August and September on account of hot weather. It will be observed that the production is given in kilograms, as 1,737,571,600 and dividing this amount by the number of flasks—50,353, we have as the contents of each flask 34,507 kilograms, which, at 2.2046 lbs. avoirdupois to the kilogram, gives the contents of the flask or bottle in English weight 76.07 lbs., or 4.03 of a pound less than is contained in the New Almaden "A" brand, which latter have a guaranteed weight of 76.50 lbs. net. To large consumers and close buyers this difference of weight and quantity in favor of the product of the New Almaden may be found worthy of note and we therefore call attention to the fact.

QUICKSILVER PRODUCTION OF THE ALMADEN MINE (SPAIN) DURING THE YEAR 1881.

Months.	Production in Kilograms.	Equal in Flasks.
January	251,503,400	7,288
February	223,961,100	6,490
March	273,743,200	7,933
April (29 days)	250,873,200	7,270
May (19 days)	192,400,200	5,578
June	.....	.....
July	.....	.....
August	.....	.....
September	.....	.....
October (12 days)	96 550,300	2,798
November	220,876,700	6,401
December	227,573,500	6,595
Totals	1,737,571,600	50,353

Equal to 34,507 kilograms per flask.

N. B.—34,507 kilograms at 2.2046 lbs. avoirdupois=76.07 lbs. avoirdupois. 75 lbs. Spanish at 1.014331 lbs. avoirdupois=76.07 lbs. avoirdupois.

IT has been proven that as a rule sagebrush or Juniper wood at $10 per cord cannot be used profitably to run quartz mills.

Quartz Mining in the Vicinity of Auburn.

The most important of the mines is the St. Patrick or Crater Hill. From this mine, or rather from its San Francisco management by stock sharps, the district owes what is known among the mining fraternity as its "black eye." Under the aforesaid management, as soon as the manipulators had unloaded the stock at a high figure under the influence of large mill returns, the ledge was lost (?) and assessments levied till the stock was again secured at a low figure. The ledge would then be found, dividends resumed, and the stock raised high enough to make a repetition of the operation profitable. This method of mining several times repeated became monotonous to investors, and the mine running behind under poor local superintendence, was attached and sold under execution. Since the sale, the mine has only been worked occasionally, but has nevertheless paid its purchase price, about $17,000, and some additional amount in dividends. The mine is worked through an incline shaft to a depth of 700 ft., this being the only shaft in the district over 200 ft. deep. Steam hoisting works take the ore out of the mine. The amount of water in the mine is comparatively insignificant, barely enough being obtained in summer time to supply the boilers. The ledge near the surface was at times quite narrow, particularly in passing through a belt of extremely hard rock from 100 to 150 ft. in depth. Below that it widened to from 2½ to 3 ft., and even more, occasionally. A pay-chute about 400 ft. long was found pitching to the east. It has been followed and worked to the east line of the mine down to the 700 level, where it passes out of the mine into the east extension owned by other parties. In the bottom of the shaft, another chute is coming in from the west, and at the present time, the shaft is being retimbered, with a view to sinking deeper and opening up this body of ore. The total yield of the mine has been in excess of $600,000.

Other important mines in the granite formation are the St. Patrick Consolidated, the Gold Blossom and its several extensions, the Mammoth and the Bowlder. All of these have been worked to some extent but to no great depth. The St. Patrick Consolidated being the east extension of the Crater Hill, is undoubtedly a valuable property, receiving from the 300 to the 700-ft. levels the great pay-chimney of that mine.

The principal differences that exist in the quartz veins that have been described, are most prominent in the mineralogical composition of the ores. Pyrite is found in greater or less quantity in all the quartz veins; in the slate formations it occurs principally in the common cubical crystallization; in the Bellevue and Crater Hill and other mines, in the granite, it often occurs in brilliant, highly-modified crystals. It is almost invariably accompanied with gold, particularly in veins in the granite. Chalcopyrite is also common but is most often found in ledges in the granite. Galena is even more common than chalcopyrite, and is found accompanying the other two. In the Conrad mine crystals of galena are found containing flakes and wires of bright gold. In nearly all mines in the granite the galena carries considerable gold, probably more gold than silver. This fact renders the treatment of these ores quite difficult. Heavy sulphureted ores assaying high figures fail to yield by the ordinary mill process one-tenth of their assay value, the bulk of the gold being run off into the tailings. There is no good reason why this should be the case. With battery amalgamation (not practiced at present) and proper sulphuret concentrators, these ores should be made to pay extremely well. Ores from the granite formation, in addition to the preceding, contain tellurium and selenium compounds; in the slate aluminium compounds and calcite, all in small quantities. Zinchlende is of common occurrence, but antimony and arsenic are not found. In the quartz deposits in the granite free coarse gold is seldom to be seen in the rock; the reverse is the case with the ledges in the slate. The sulphuret concentrations which are principally iron pyrite vary from $75 to $500 per ton. The great bulk assay $150 per ton and upward.

During the year a sulphuret reduction works known as the Auburn Chlorine Works, has been built and commenced work under the superintendence of Mr. A. Maltman. The roasting furnace used is a two-hearth reverbatory step furnace, having a working capacity of about 4,000 lbs. in 24 hours. The chlorine process is used for extracting the gold, and the residues are then treated by the hyposulphite of soda process for the silver. In the aggregate about 150 tons of sulphurets were treated, yielding in round numbers about $7,000 in gold and $1,500 in silver. The efficiency of treatment is claimed to be about 87% of assay value.

In milling facilities the district is quite deficient; there are two small five-stamp custom mills, which do fair work with rock containing coarse free gold, but which are utterly unable to work sulphureted ores, having only the most primitive apparatus for concentrating tailings. The St. Patrick or Crater Hill mill contains 15 stamps and six old style Hendy pans for concentration. It is much superior to the others noted, but is still far behind the requirements of the district. What is needed is a well constructed mill, containing very complete ore dressing or concentration plant. Before the tailings from the battery can be properly concentrated a preliminary sizing of the particles is needed, which can be secured by jiggers or similar apparatus.

(CONCLUDED.)

Notes on Mica.

[Written for the PRESS by HENRY G. HANKS, State Mineralogist.]

Mica is made a substitute for glass in certain cases where that material cannot be used, as in front of stoves, bakers' ovens, furnaces, certain lanterns, lamp chimneys, windows in ships of war, as such windows cannot be broken by the concussion of the guns. In chemistry it is sometimes used as a support for substances to be fused, and as thin covers for microscopic objects where it is desirable to have the cover thinner than can be attained by glass; it also used in the pans of the balance upon which to place powders and damp or corrosive substances to be weighed. In this case two pieces of equal size and weight are used which counterpoise each other.

Mica is also applied to ornamental purposes. In paper hangings and decorative work it is ground or otherwise separated into a fine scaly powder and sifted over the work in a kind of frosting which is made to adhere by a coating of glue size or paint. Mica of a yellow color is said to be used in the manufacture of artificial aventurine.

Mica is a Latin word, meaning a crumb or grain—little bit—morsel.

Mica salis is literally a grain of salt, but figuratively a grain of sense.

"*Nulla in tam magno est corpore mica salis.*"

The name was probably given to the mineral because it was generally found in small grains or flakes in mica schist, or mixed with the sands of streams in minute particles. There seems, however, to be a diversity of opinion, for some writers claim that the name is derived from the Latin *micare* or *mico*, words meaning to shine, glitter, flash, or gleam. The German word *glimmer*, in that language applied to mica, is derived from the same idea.

The name mica was given by Hauy, and glimmer by Werner.

Mica forms the scales in aventurine, which is vitreous quartz with spangles of gold-colored mica interspersed through it. There is a vase of aventurine in the Museum of Practical Geology, in London, bequeathed to that institution by Sir R. I. Murchison, to whom it was presented by the Emperor Nicholas I, of Russia. It measures four feet in hight and six feet in circumference. It is supported on a pedestal of polished gray porphyry. A similar vase and the only other one in the world was presented to Humboldt, and is now in the Royal Museum at Berlin.

Fine specimens of a variety of aventurine called star stone are brought from Sweden. This stone is white quartz in which small silvery scales of mica are interspersed.

Sedimentary rocks, resulting from the decomposition of the crystalline rocks, and especially granite, contain mica as one of the constituents.

There seems to be considerable doubt as to the identity of the mica in mica basalt. Dana thinks that the mineral claimed to be mica is a pseudomorph after olivine, altered by the oxidation of the iron.

The associates of mica are quartz, black tourmaline, indicolite, ruhellite, orthoclase and other feldspars, garnet, topaz, hornblende, beryl, lepidolite, cookeite, cassiterite, apodumene, amblygonite, dolomite, magnetite, siderite, pyrite, chalcopyrite, andalusite, pinite and other minerals.

The minerals which are now recognized or classed as micas may be summed up as follows: Astrophyllite, biotite, cryophyllite, lepidolite, lepidolomelane, muscovite and phlogopite. The following micaceous minerals are principally varieties of the micas, while some authors give to some of them a specific position in their works:

Alurgite, adamsite, aspidolite, cookeite, damourite, didrimite, eucamphite, epiphanite, euphyllite, hallite, helvertan, manganophylle, nacrite, odinite, phengite, paragonite, pregaratite, pterolite, pihlite, ruhellane and sericite.

According to Prof. Silliman, muscovite is the species generally found in the granitic rocks, and the phlogopites in serpentine and granular limestone.

Astrophyllite is a rare bronze-yellow or golden-yellow mica, which occurs in long narrow tabular crystals. It is a silicate of iron, manganese, magnesia, lime, soda, potash and alumina, with titanic acid and zirconium. It is a beautiful mineral but has no commercial value. Its hardness is 3, and specific gravity 3.324. Before the blowpipe it swells and fuses to a black magnetic globule. With borax, gives a strong reaction for manganese. It is decomposed by boiling hydrochloric acid with separation of silica. Its powder resembles mosaic gold. Named from its stellate crystals.

Biotite—called also hexagonal mica, and iron magnesia mica—is rather a common mineral, which has the following properties: Luster, splendent, more or less pearly; color, green to black, sometimes black, even in thinnest laminae, blood red or brown by transmitted light. It is a hydrous silicate of alumina, iron, magnesia and potash, with fluorine and titanic acid, in proportions which vary in different specimens. It is named after Biot, a French naturalist. The chemical properties resemble those of phlogopite, which will be described. Ruhellan is an altered biotite.

Cryophyllite is a fusible emerald-green mica—a silicate of alumina, potash and lithium, with other constituents in small proportions; found only at Cape Ann, Mass., in granite. It has the remarkable properties of fusing in the flame of a candle, and being decomposed by dilute acids.

Lepidolite is a lithium mica, so named by Kirwan from two Greek words meaning "scaly stone." Its luster is pearly; color, rose red to violet gray, lilac, yellowish, grayish white, white. This mica, which is not common, is a constituent of certain granites and gneiss. It has no economic value unless for the extraction of the lithium, of which it contains about 5% to 6%. Lepidolite is essentially a silicate of alumina, lithium and potash, containing also manganese and fluorine. Its hardness is 2.5 to 4 0; gravity, 2.84 to 3.0. In a closed tube it gives water and reacts for fluorine. Fuses before the blowpipe to a white or grayish glass, which is sometimes magnetic; with hydrochloric acid tinges the blowpipe flame red for a moment only.

This beautiful mineral occurs in abundance in San Bernardino county, Cal., the exact locality not yet being given. It is associated with erythrite (arseniate of cobalt) and ruhellite (red tourmaline). Specimens may be seen in the State museum.

Lepidomelana—This is an iron potash mica containing silica, alumina, sesquioxide and protoxide of iron, manganese, magnesia, lime, potash soda, and water in varying proportions. It occurs in small, six-sided tabular crystals, or in an aggregation of small scales. It is unknown in California. This mica is fusible at a high heat to a magnetic black globule. In hydrochloric acid it is decomposed with the separation of silica. Its luster is pearly to adamantine; color, generally black; sometimes green by reflected light; streak, gray green; opaque in mass, but translucent in thinnest scales; laminæ somewhat brittle. This mica is named from two Greek words implying black scale. It has no economic value. Annite, hastonite and pterolite are varieties of this mineral.

Muscovite, called also rhombic mica and hinoxide mica, is the common mica of commerce. It was named by Dana, in 1850, from "Muscovy glass," the common name, as before mentioned. It is one of the constituents of the granites, gneiss, mica schist and some of the sedimentary rocks. It is a potash mica, which plays an important part in the natural formation of soils, and is probably the source of the potash in plants and the potash minerals of the secondary formations. The constituents of muscovite are silica, alumina, protoxide and sesquioxide of iron, lime, soda, potash, water and fluorine; but the proportions are so different in different localities that no single analysis would have any value if given here. The colors also vary as much as the composition. The following variety of colors are known: White, silvery white and grayish white, rose, clear pale rose and gray ross, black and greenish black, green, emerald green, (fuchsite), faint green, brownish green, pale green, clear olive green, olive green and blackish green, brown with patches, dark brown, light brown, violet brown, smoky brown, pinchbeck brown and whitish brown, gray, violet gray and greenish gray, yellow and greenish yellow, white, brownish white and greenish white, blonde, grayish blonde and yellowish blonde, colorless, pearly, and giving a silvery reflection.

The hardness of muscovite is 2 to 2.5, specific gravity, 2.75 to 3.1. Before the blowpipe it whitens and fuses on the thinnest edges to a gray or yellow glass. With the fluxes it gives a reaction for iron, and sometimes for manganese and chromium. In a closed glass tube it gives a little water, and with Brazilwood paper the reaction for fluorine; the laminæ are very flexible, tough and elastic.

Fuchsite, named from the chemist Fuchs, is a chromium muscovite, sometimes containing as much as four per cent. of the oxide of chromium. Margarodite is a hydrous potash mica altered from muscovite by hydration, which it resembles both in crystallization and appearance.

The largest sheets of Pacific coast muscovite which have come to the notice of the State Mining Bureau are those in the museum numbered 2,160, and presented by the late Joseph Mosheimer. They are from New Mexico.

Phlogopite, or Rhombic Mica, sometimes also called magnesia mica, is a silicate of magnesia, alumina and potash, with small proportions of other constituents. A sample from Gouverneur, New York, gave to Rammelsberg the following analysis:

Silica	41.96
Alumina	13.47
Protoxide of Iron	2.12
Oxide of Manganese	.55
Magnesia	27.12
Lime	.34
Soda (trace)	———
Potash	9.37
Water	.60
Fluorine	2.93
	98.46

Phlogopite is characteristic of the serpentines and limestones. It is sometimes found in crystals of great size; one in the cabinet of W. W. Jefferis is 20 inches long, 4 inches thick at the top by 8½ inches in the center. This remarkable crystal weighs 57½ lbs.

The color of phlogopite is yellowish brown, sometimes copper-colored. In thin sheets it is translucent or transparent. The laminæ are tough and elastic. No. 1404 in the State Museum is a fine specimen of the copper-colored variety found at Burgess, Canada. The hardness of phlogopite is 2.5 to 3.0; gravity, 2.78 to 2.85. In closed tubs it gives water; before the blowpipe, turns white and fuses on the thinnest edges. It is decomposed by boiling hydrochloric acid, silica separating. This mica is seldom found in sheets large enough to be useful in the arts, and it has therefore no economic value. It is named from a Greek word meaning fire-like.

The following is a list of the mica minerals in the State Museum. The figures are the catalogue numbers:

159. Mica, Muscovite.—El Dorado county, Cal.
460. Garnets in Mica Schist.—Sitka, Alaska.
608. Lepidolite.—Middletown, Conn.
617. Muscovite.—Middletown, Conn.
738. Mica Schist.—Gold Lake, Plumas county, Cal.
1092. Mica Schist.—Ivawatt district, San Bernardino county, Cal.
1404. Copper Mica, Phlogopite.—Burgess, Canada.
1408. Mica.—Canada.
1626. Mica Schist.—Found at the ruin of Casa Grande, Pinal county, Arizona, lying on the ground in considerable quantities. Probably used in the manufacture of pottery.
1821. Mica Schist.—Philadelphia, Penn.
2031. Mica Crystal.—Paris, Maine.
2126. Jefferisite.—Susanville, Lassen county, Cal.
2160. Mica, Muscovite.—New Mexico.
2481. Muscovite Mica.—Near Tucson, Pima county, Arizona.
2953. Muscovite.—Pennsbury, Penn.
29 6. Plumose Mica, Muscovite.—Salsbury, N. H.
2980. Phlogopite.—St. Lawrence county, N. Y.
3061. Phlogopite.—Burgess, Canada.
3073. Phlogopite.—Templeton, Ottawa county, Canada.

To ascertain the price of mica in San Francisco two samples were bought at a retail stove store; one was five by six inches and the other two and one-half by five inches, and the thickness being measured with a Jackson micrometer, it was found that it would require a pile of 133 such sheets to make an inch. They were weighed, and the smaller required 119 sheets to the pound and the larger 68 sheets. The price paid for them was at the rate of $11.86 for the smaller and $13.70 for the larger. By this it will be seen how high a price the consumer is compelled to pay for this mineral in small quantities. Mr. Jacoby in his letter has given the price that the European manufacturers are willing to pay for it.

(CONCLUDED.)

A NEW GENTIAN—(Gentiana Micrncalyx.)

A New Gentian.

[Read at a recent meeting of the California Academy of Sciences, by J. G. LEMMON.]

Gentiana microcalyx, Lemmon (summit of the Chiricahua mountains, in southeastern Arizona, Sept. 30, 1881)—Comparing this plant with descriptions in Dr. Gray's late synopsis of the genus *Gentiana*, we find that it belongs in his first section, *Gentianella*, annuals having the corolla destitute of extended plaits, lobes or teeth at the sinuses; the anthers are versatile, and, at first, introrse, at length turning outward, with stigmas distinct. It falls into the second sub-section—flowers funnel-form, lobes entire, capsule sessile. Its characters are farther limited to this subdivision, with peduncles short, terminal or lateral; the stems distinctly wing-margined.

Farther than this, the plant remains undescribed. Its nearest allies have either crowns of setæ or hairs in the throat of the corolla, or their calyx-lobes are dissimilar or are conspicuously foliaceous or spathaceous; while in this gentian there are no setæ, and the calyx is regular and very small—suggesting the specific name given of *microcalyx*.

This species grows to a hight of from eight inches to two ft. The stems are quadrangular, wing-margined, branching from all the nodes in even ranks; glabrous throughout; the leaves from lanceolate to narrowly oblong, one to two inches long, the lowest shorter, all sessile and narrowed at base, three to five-nerved; calyx very small, five-cleft to the middle; the teeth lanceolate, half a line long; the tube 10-castate; flowers half an inch long, white, becoming greenish-yellow in drying; lobes four or five spreading, lanceolate, one-third to one-half the length of the tube, attenuate to a subulate point; anthers large, black, exserted; filaments long, broad and flat; capsule sessile, bursting the withering corolla; seeds numerous, small, reticulated. A strikingly beautiful white gentian, that would be a valuable acquisition to our gardens and conservatories.

In the engraving the plant is shown, cut in two parts, for the convenience of the engraver; *a*, is the calyx opened out; *b*, the flower displayed, calyx in position, corolla opened revealing the ovary; *c*, is ovary enlarged, showing the two flat, strap shaped, stigmas; *d*, the ovary, natural size; *e*, is the atamen, with its double anther, enlarged.

SAFETY APPARATUS FOR MINERS.—At a recent meeting of the Manchester Geological Society, Mr. J. S. Martin, inspector of mines, read a communication which he had received from Messrs. Forster & Fleuss, descriptive of their patent noxious gas apparatus and patent miners' safety lamp. The noxious gas apparatus comprised a knapsack arrangement by which the wearer's breath was filtered of its carbon dioxide and moisture, and after being revivified by admixture with pure oxygen, was again taken in by the lungs. It was claimed that by means of this apparatus, explorers would be enabled to penetrate safely into workings filled with gas. The lamp was a modification of the lime light, self contained and portable. The chairman suggested that the apparatus might also be useful in mills, factories and theaters in case of fire.

DIGGING the streets for mining purposes is a question that threatens to produce some excitement in the near future at Sonora, Tuolumne county.

CHICAGO **FRASER & CHALMERS,** ILLINOIS.

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 9x10 to 18x60. This latter size furnished J. B. Haggin for Giant and Old Abe Co., Black Hill s also Corliss Pumping Engines, 26x60, for Hoisting and Pumping Works, for 2,000 feet deep. **Baby Hoists for Prospecting, 4 H. P. to 6 H. P.**

Wire Rope, Safety Cages and any Size and Forms of Cars.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail.

HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,750 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x30 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. BOILERS of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

McCaskell's Patent Car Wheels and Axles—Best in Use.

New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

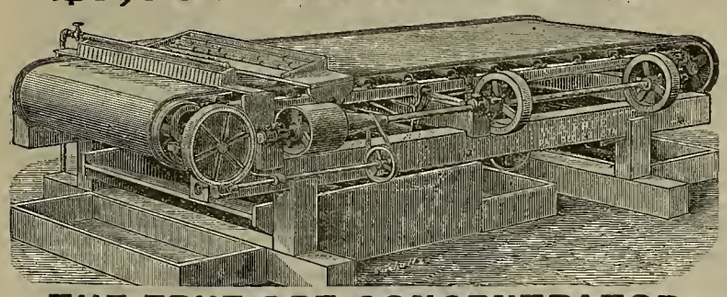
PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street - - San Francisco, Cal.

$1,000 CHALLENCE!



THE FRUE ORE CONCENTRATOR.

Nearly 300 are now in use, giving entire satisfaction. Awarded First Premium and Silver Medal at the Industrial Fair for 1880 of the Mechanics' Institute of San Francisco, Cal.

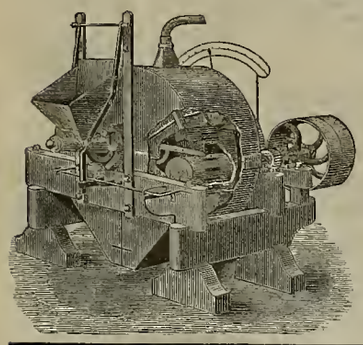
Saves from 50 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal; water required is less than in any other wet Concentrator; the power required per machine is less than one-half horse power; the labor required is light, one man on a watch can attend to sixteen machines.

We challenge any other Concentrator in use for a fair and impartial competitive trial, side by side, for stakes of $1,000 each, and we mean business.

☞A machine with all improvements can be seen in working order and ready to make tests, at the offices of Hinckley, Spiers & Hayes, 220 Fremont street.

ADAMS & CARTER, Agents, Room 7 No. 109 California Street, S. F.

TUSTIN'S ROTARY PULVERIZING MILL.



WORKS ORE WET OR DRY,

And Feeds Itself Automatically.

Patented October 11, 1881.

One of these machines can be seen at the Ore Sampling and Pulverizing works of Hofmann Bros., No 415 Mission St., where it is working every day. Weight 5,000 lbs, heaviest piece 480 lbs.

Manufactured at the

TUSTIN WINDMILL, HORSE POWER AND PUMPING MACHINE WORKS.

308 Mission Street, S. F., Cal.,

By W. I. TUSTIN, Inventor and Patentee.

ENGINE LATHES IN SECTIONS.

Limit of weight for 25-inch Lathes, 300 pounds. For 17-inch Lathes, 150 pounds.

Standard and Special Machine Tools.

SAN FRANCISCO TOOL CO., No. 21 Stevenson St., San Francisco.

DEWEY & CO.'S

Scientific Press **Patent Agency.**

[ESTABLISHED 1860.]

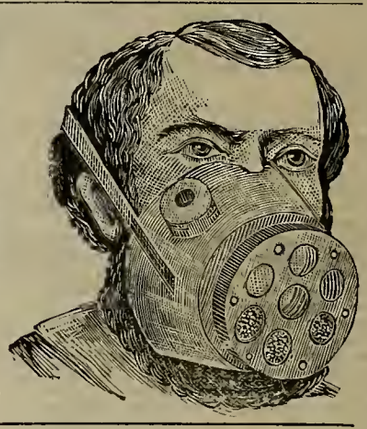
Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 252 Market St., S. F.

A. T. DEWEY. W. B. EWER. GEO. H. STRONG.

PATENT

LIFE-SAVING RESPIRATOR

Prevents Lead Poisoning and Salivation.



INVALUABLE to those engaged in Dry Crushing Quartz Mills, Quicksilver Mines, Guano Works, White Lead Corroding, Feeding Threshing Machines and all occupations where the surrounding atmosphere is filled with dust, obnoxious smells or poisonous vapors. The Respirators are sold subject to approval after trial, and if not satisfactory the price will be refunded. Price, $3 each, or $30 per dozen. Sent post-paid to any address upon receipt of price. Address all communications and orders to

SETH MARSHALL, Grand Hotel,

Or care of C. C. HARVEY,

309 California Street, S. F., Cal

Mining Engineers and Metallurgists

JOHN TAYLOR & CO.,
IMPORTERS OF AND DEALERS IN
Assayers' Materials,
MINE and MILL SUPPLIES,
CHEMICAL APPARATUS AND CHEMICALS, DRUGGISTS' GLASSWARE AND SUNDRIES, Etc.
118 and 120 Market Street, and 15 and 17 California St., San Francisco.

We would call the attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our full stock of Balances, Furnaces, Muffles, Crucibles, Scorifiers, etc., including, also, a full stock of Chemicals.
Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast, we feel confident from our experience we can well suit the demand for these goods both as to quality and price. Our *New Illustrated Catalogue*, with prices, will be sent on application.
☞Our Gold and Silver Tables, showing the value per ounce Troy at different degrees of fineness, and valuable tables for computation of assays in grains and grammes, will be sent free upon application. Agents for the Patent Plumbago Crucible Co., London, England.
JOHN TAYLOR & CO.

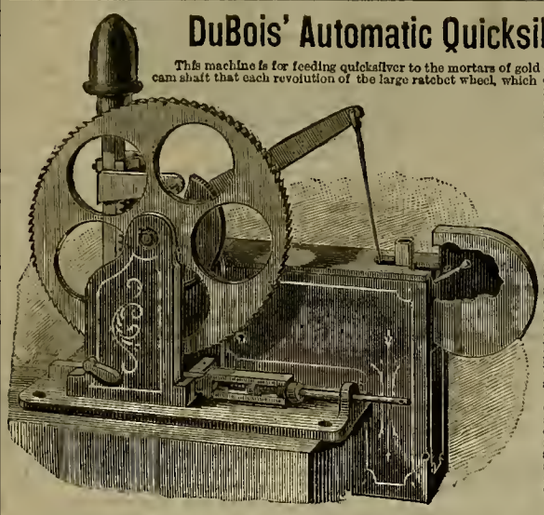
SHEET IRON PIPE.

FRANCIS SMITH & CO.,
Manufacturers of
THE PATENT CHANNEL IRON WHEELBARROWS.
THE STRONGEST BARROW MADE. These Barrows are made by Superior Workmen, and of the best material. All sizes kept constantly on hand

SHEET IRON PIPE.
Lap-Welded Pipe, all Sizes, from Three to Six Inches. Artesian Well Pipe. Also, Galvanized Iron Boilers, from 25 to 100 Gallons.
Iron Cut, Punched, and Formed for making Pipe on ground, where required. All kinds of Tools supplied for making Pipes. Estimates given when required. Are prepared for coating all size of Pipes with a composition of Coal Tar and Asphaltum.
Office and Manufactory, 130 Beale Street, San Francisco.

SHEET IRON PIPE.

DuBois' Automatic Quicksilver Feeder.

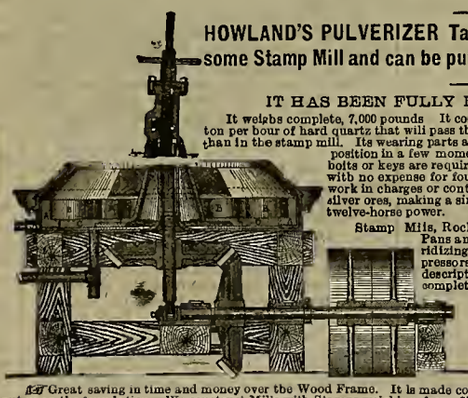


This machine is for feeding quicksilver to the mortars of gold mills. It is so connected to the cam shaft that each revolution of the large ratchet wheel, which can be regulated to revolve once in one, two, three or four minutes, as desired, dips a small cup into a reservoir of quicksilver, and by a trip of the cam, empties the contents into a pipe leading down to the mortar, supplying an exact quantity at regular intervals, superseding the ordinary hand feeding, which is of necessity subject to great irregularity, and liable to neglect. It renders the amalgamation of all the gold in the pulp equally certain and perfect.
The mechanism to produce this depression and elevation of the cup, is driven by the cam shaft, similarly to the self-feeders, over which so much ingenuity has been expended to regulate the delivery of ore to the mortar. As it is to be desired to have the ore go in constantly and regularly, so it is equally desirable to have the mercury fed constantly and regularly.
A chief point of excellence of this machine is, that it allows the quantity of mercury which would be otherwise fed in mass, in one hour, to be subdivided into a number of small portions, and fed almost continuously; *i. e.*, from every one to four minutes.
Price, complete, $100.

For Sale by **WHITNEY & MARSHALL,** Sole Agents
22 & 24 Fremont St., San Francisco.
Dealers in Iron, Steel, Hardware and Mining Supplies, Wrought Iron Pipe and Fittings, Pump Columns, Wire Rope, etc. A large stock of Boiler, Plate and Sheet Iron of every description.

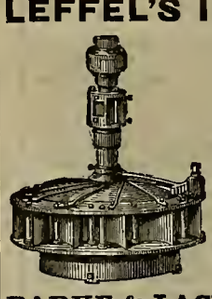
MOREY & SPERRY,
MANUFACTURERS OF
Gold and Silver Grinding and Amalgamating Machinery

HOWLAND'S PULVERIZER Takes the Place of the Cumbersome Stamp Mill and can be put up in one day ready for work.



IT HAS BEEN FULLY PROVED AND TESTED.
It weighs complete, 7,000 pounds It costs $1,500 ready for the belt Will crush one ton per hour of hard quartz that will pass through a 40-mesh screen. The wear is less than in the stamp mill. Its wearing parts are plain castings and can be dropped into position in a few moments, as shown by the letters A, B and C, no bolts or keys are required; it can be set upon the floor of a mill with no expense for foundations, and can be used to crush and work in charges or continuous. It will amalgamate either gold or silver ores, making a simple, cheap and effective mill, it requires twelve-horse power.
Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver ores Chloridizing Furnaces, Retorts, Rock Drills Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies Iron Work complete for Wood Frames, also
SPERRY'S WROUGHT IRON FRAME FOR STAMP MILLS.
☞Great saving in time and money over the Wood Frame. It is made complete with Wrought Iron Frame ready to put upon the foundation. We construct Mills with Stamps weighing from 350 to 900 pounds for Gold and Silver Ores. Wet or Dry Crushing Mortars.
MOREY & SPERRY—Warerooms, 92 and 94 Liberty St., N. Y.

LEFFEL'S IMPROVED WATER WHEEL.



PRICES REDUCED!
PATENTS REISSUED 1868.
The "OLD RELIABLE" with improvements, making it
THE MOST PERFECT TURBINE NOW IN USE.
Comprising the **Largest** and the **Smallest** Wheels, under both the **Highest** and **Lowest** head used in this country. Our new Illustrated Book sent free to those owning water power.
Those improving water power should not fail to write us for **New Prices**, before buying elsewhere. New Shops and New Machinery are provided for making this Wheel. Address
JAMES LEFFEL & CO., Springfield, Ohio, and 110 Liberty St., N. Y. City.
PARKE & LACY, Sole Agents, 21 and 23 Fremont St., S. F.

STEEL CASTINGS

FROM 1-4 TO 10,000 lbs. WEIGHT.
True to pattern, sound and solid, of unequaled strength, toughness and durability.
An invaluable substitute for forgings or cast-iron requiring three-fold strength.
Gearing of all kinds, Shoes, Dies, Hammerheads, Crossheads for Locomotives, etc.
15,000 Crank Shafts and 10,000 Gear Wheels of this Steel now running prove its superiority over other Steel Castings.
CRANK SHAFTS, SHOES, DIES and GEARING specialties. Circulars and Price Lists free. Address
CHESTER STEEL CASTING CO.,
Works, CHESTER, Pa. 407 Library St., PHILADELPHIA

SELBY SMELTING and LEAD CO.,
416 Montgomery St., San Francisco.
Gold and Silver Refinery And Assay Office.
HIGHEST PRICES PAID FOR
Gold, Silver and Lead Ores and Sulphurets.
Manufacturers of Bluestone.
ALSO, LEAD PIPE, SHEET LEAD, SHOT, ETC.
This Company has the best facilities on the Coast for working
GOLD, SILVER and LEAD
IN THEIR VARIOUS FORMS.

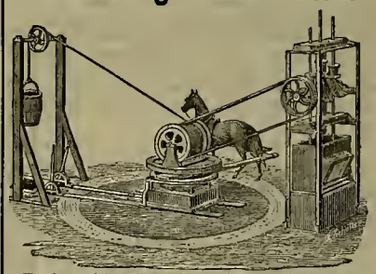
JOHN A. CHURCH, E. M. PH. D.
MINING ENGINEER,
Room 75, 115 Broadway, New York.
☞Agent for PADDOCK'S Ore Dressing Machinery. Mining Machinery supplied.

San Francisco Cordage Factory.
Established 1856.
Constantly on hand a full assortment of Manilla Rope, Sisal Rope, Tarred Manila Rope, Hay Rope, Whale Line, etc., etc.
Extra sizes and lengths made to order on short notice.
TUBBS & CO.,
611 and 613 Front Street, San Francisco

New Mining Horse Power.



The demand for a better Horse Power, suited to more general use, has resulted after much experience in the above machine, which we can recommend as a First-class Hoisting Power, under complete control of man tending bucket, through levers connecting with brake and clutch.
This power is light and strong, so that two or more horses can be used for crushing ore or other work.
C. H. BAKER,
Agent and Manufacturer of Mining Machinery
38 and 40 Main St., S. F.

N. W. SPAULDING'S

PATENT DETACHABLE TOOTH SAWS,
Manufactory, 17 & 19 Fremont St., S. F.

Palmer's Safety Clutch
FOR
ELEVATORS
Will be Applied to Elevators on Short Notice.
☞It is now used in the U. S. Army Building and Grand Hotel, New Montgomery Street.
Agency, 303 Montgomery St., S. F.

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

From the official list of U. S. Patents in DEWEY & Co.'s SCIENTIFIC PRESS PATENT AGENCY, No. 252 Market St., S. F.

FOR THE WEEK ENDING FEBRUARY 7, 1882.

253,251.—BODY-BRACE—Jas. W. Anderson, Bodie, Cal.
253,258.—SCREW PROPELLER—J. Belduke, S. F.
253,349.—STORE-COUNTER SEAT—A. J. Culbertson, San Andreas, Cal.
353,267.—WATER WHEEL—R. N. Davidson, Weaverville, Cal.
253,303.—FISH HOOK EXTRACTOR—J. W. Foard, S. F.
253,255.—SEEDER AND CULTIVATOR—John E. Henris, Dixon, Cal.
253,300.—LIFTING JACK—F. Lehman, Milwaukee, Ogn.
253,314.—LATHE ATTACHMENT—Henry Richmann, S. F.
253,229.—CONCENTRATOR—J. F. Saunders, Ogden, U. T.
253,462.—ATTACHMENT FOR FURNACES—M. F. Wood, S. F.
253,186.—ORNAMENTATION OF GROUNDS—H. D. Cogswell, S. F.

FOR THE WEEK ENDING FEBRUARY 14, 1882.

253,693.—GRIPE FOR PROPELLING CARS—R. F. Bridewell, San Francisco, Cal.
253 677.—WATER CLOSET—J. Budde, S. F.
253,594.—HAIR TONIC—Lewis Forbes, S. F.
253,596.—SOFA BED AND LOUNGE—A. S. I. Gabbs, S. F.
253,620.—TREADLE POWER FOR GRINDSTONES—J. M. Nelson, Oakdale, Cal.
253,556.—PROCESS OF AND APPARATUS FOR DRYING LUMBER—Jas. Randall, S. F.
253,642.—CLASP FOR CORSET STIFFENERS—Mrs. C. V. Turner, Nicola Valley, B. C.
253,644.—FRICTION BRAKE FOR STEERING WHEELS—Walker C. Tyler, Stockton, Cal.
253,649.—EXPLODER FOR FIRING BLASTS—Alex. Watson, San Francisco, Cal.
253,650.—HAY WAGON—E. M. White, Elhi, W. T.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast Inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

CLASP FOR CORSET STIFFENERS.—Christina V. Turner, Nicola Valley, B. C., assignor of one-half to D. K. McMullen, S. F. No. 253,642. Dated Feb. 14, 1882. This invention relates to a device for fastening the whalebones or stiffeners in corsets, and for protecting the corsets from the wear of the ends of the stiffeners. It consists of a small metal clip having points, which pass through the cloth on each side of the stiffeners and are clasped behind, the top being provided with an extension for the insertion of an eyelet, and the whole device being pressed down upon and on both sides of the stiffeners. This device has for its object the holding of the stiffeners in place and the prevention of wear by means of the ends of the stiffeners being forced through the cloth.

TREADLE POWER FOR GRINDSTONES.—Joshua M. Nelson, Oakdale, Stanislaus county. Dated February 14, 1882. No. 253,620. This treadle power for grindstones consists in the combination and arrangement of parts whereby a regular and continuous motion may be imparted to the stone, securing at the same time the comfort of the operator. More particularly, it consists of a suitable frame or stand carrying a grindstone and water trough, motion being transmitted to said stone from suitable treadle levers through the intermediate mechanism of sprocket wheels or other similar devices attached to the stand.

FRICTION BRAKES FOR STEERING WHEELS.—Walker C. Tyler, Stockton. No. 253,644. Dated Feb. 14, 1882. This invention relates to steering wheels applied brakes are necessary or convenient, and the details of construction are such that the inventor can apply the brake to steering wheels already constructed. A strap encircles the wheel, and when pressure is brought to bear on a lever, the ends of the hand are brought together upon the rim. The force of this friction brake is exerted equally on the wheel. These wheels are not usually strongly journaled, so that any great side pressure would tend to injure them.

DREDGING MACHINE.—Zephaniah Williams, Oakland. No. 253,145. Dated Jan. 31, 1882. This patent covers improvements on a dredger which was patented by the same inventor in March, 1880. He adds to the dredger two vertical towers so that he can run a double set of buckets either from or to the scow, in the same direction, and thus one set can carry its work up to where the other began, and on the return swing the other can work up to the first. More work can be done with this machine. Elaborate drawings would be necessary to elucidate all the details.

HAIR TONIC.—Lewis Forbes, S. F. No. 253,594. Dated Feb. 14, 1882. This composition consists of certain peculiar ingredients combined in suitable proportions, which, applied to the head, is intended to produce and restore hair. The application is by rubbing the scalp after first carefully shaving it. This operation is continued until the desired effect is produced.

THERE were shipped from Humboldt bay last year, 59,755,396 ft. of lumber, 38,905,750 shingles, 2,918,700 shakes, and 46,145 posts.

Recent Contributions to the California State Mining Bureau.

[Furnished for publication in the MINING AND SCIENTIFIC PRESS by HENRY G. HANKS, State Mineralogist.]

[CATALOGUE.]

Silver Ore with Cinnabar—Barcelona mine, Nye county, Nev. (See No. 2412.) W. Craig.
Silver Ore, Horn Silver—Kentucky mine, Sweetwater range of mountains, Mono county, Cal. J. S. Frost.
Cast of the Horns of the Bison Latifrons (Leidy)—Cincinnati Society of Natural History.
Unio Crassidens (Lam.)—Ohio river.
Unio Cicatricosus—Ohio river.
Unio Varicosus (Lea.)—Ohio river.
Unio Pressus (Lea.)—Ohio river.
Unio Phaseolus (Hil'd)—Ohio river.
Calcite—Nevada.
Amethyst—Lake Superior.
Pearl Spar-Dolomite—Niagara river, New York.
Cryolite—Greenland.
Lithographic Stone—Kentucky.
Quartz Crystals—Arkansas.
Red Granite—Missouri.
Copper Pyrites—Rockwood, Tenn.
White Steatite—Massachusetts.
Native Copper—Lake Superior.
Actinolite in Talc—Newfane, Vermont.
Mammillary Chalcedony (Geode)—Iowa.
Gypsum, Plumose—Kentucky.
Black Tourmaline in Quartz—Ohio.
Green Talc (Foliated) in Calcite—Ohio.
Calcite, Dog Tooth Spar—Niagara Falls, New York.
Beryl—Bolton, Mass.
Hematite—Rockwood, Tenn.
Galena Crystals—Galena, Ill.
Tourmaline in Steatite—Plymouth, New Hampshire.
Sphalerite (Zinc Blende) in Calcite, Liberty, Kentucky.
Rusophycus Bilobatus, Lower Silurian Fossil—Cincinnati Group, Ohio.
Lithostroti on Basaltiformis, Sub-Carhonifeorous Fossil—Ohio.
Columnaria Alveolata, Lower Silurian Fossil—Cincinnati Group, Madison, Indiana.
Dalmantis Linularis, Upper Silurian Fossil—Niagara Group, New York.
Monticulipora Pillasa, Lower Silurian Fossil—Cincinnati Group, Hamilton, Ohio.
Megalomus Canadense, Upper Silurian Fossil—Niagara Group, Gault, Ontario.
Endoceras Magniventrum, Lower Silurian Fossil—Cincinnati Group, Hamilton county, Ohio.
Pentamerous Ohlongus, Upper Silurian Fossil—Niagara Group, Ohio.
Gold Quartz—Mohmann mine, Big Oak Flat, Tuolumne county, Cal. A. D. Miesegaes.
Ferruginous Quartz with Gold in a Cavity Formerly Occupied by a Large Crystal of Pyrite—Modesto mine, Beveridge mining district, Inyo county, Cal. T. McDonough.
Piece of Indian Sculpture (Very Fine)—British Columbia. George Kinney.
Crystallized Mineral Containing Carhonates of Copper and Lime—It is anhydrous, and gives a white precipitate with ammonia. A full analysis will be made of it in the future. Copper Queen mine, Bisbee, Arizona. George Madeira.
Calcite Crystals—Argus mountains, Inyo county, Cal. Mrs. S. A Gale.
Spear Head of Obsidian—San Rafael, near the cemetary. G. F. Beardsley.
Country Rock with Section (Trachyte)—Rocky Bar mine, Grass Valley, Nevada county, Cal. J. D. Coughlin.
Country Rock with Section for the Microscope (Trachyte)—Rocky Bar mine, Grass Valley, Nevada county, Cal. J. D. Coughlin.
Dialogite Crystals (Very Fine)—Colorado mine No. 2, Monitor district, Alpine county, Cal. Geo. F. Beardsley.
Magnetite—Near the New England mills, Placer county, Cal. J. R. Scupham.
Cement Nodules—Glenbrook, Lake county, Cal. Found in a bluish clay covering an area of 10 acres. H. A. Aldrich.
Argentiferous Galena Showing a Radiated Structure—Brown Monster mine, Inyo county. S. D. Woodhull.
Vivianite—Brea ranch, Los Angeles county, Cal. J. W. Redway.
Nodules or Obscure Fossils—Buena Vista mountain, near Cerro Gordo, Inyo county, Cal. M. A. Wheeler. These are the same as No. 1512, which were thought to be paleozoic fossils.
Ulexite, Showing the Two Varieties—Ten tons of boracic acid has been produced from this material by the Phœnix Chemical Works at the town of Columbus, Esmeralda county, Nev. H. S. Durden.
Boracic Acid—Manufactured by the Phœnix Chemical Works, from Esmeralda county, Nev. H. S. Durden.
Calcite, Botryoidal—Cresswell ranch, Curry county, Oregon. W. B. Mason.
Chloride of Silver, Fused—Obtained from 10 lbs. of ore from the Cerro Fasco mines of Peru. William Hall.
Indian Stone Implement—San Pablo, Contra Costa county, Cal. J. Z. Davis. This was probably used in spinning. There are in the Museum six others of like form and size from different localities in the State.
Spear Head of Obsidian—Found with the last at San Pablo, Contra Costa county, Cal. J. Z. Davis.
Gold Quartz—Very rich. Keynot mine, Beveridge district, Inyo county, Cal. J. H. Holt. This specimen is peppered with fine gold which can only be seen by close inspection.
Tusk of an Elephant.-(Elephas Primigenius) Elephant Point, Behring Straits. James Wayson.
Large Specimen of Coal—Shores of Arctic Ocean. James Wayson.
Iron Ore with Fossils—Found with the last, shores of the Arctic Ocean. James Wayson.
Perfect Tusk of the Hairy Mammoth—(Elephas Primigenius). Brought from 2,000 miles up the Yukon river, Alaska. Lon Cox, Chief Engineer of the steamer *St. Paul*. This is a rare, beautiful and interesting specimen.
Chrome Iron of High Grade—From within half a mile of the town of Yreka, Siskiyou county, Cal. Dr. F. G. Hearn.
Aragonite—White and pure, Johnsville, Plumas county, Cal. W. M. Pratt. This mineral has the property of being easily reduced to a powder, and will no doubt be used as a substitute for chalk in chemical manufacture.

The Idaho's Big Pump.

A short time since we gave a detailed description of some new and heavy pumping machinery being made at the Union Iron Works, in this city, for the famous Idaho Gold mine, at Grass Valley. This machinery has now been started up, and the Grass Valley *Union* has this to say about it: For months past the Idaho Mining Co. has been preparing to set up additional pumping machinery, to relieve the strain upon the engine in use, and to provide for any contingency of an increased amount of water, should such occur; and everything now being in readiness, the new and powerful engine will be started up for regular work to-day. Up to the present time, the large engine in use has pumped all the water from the mine, different sized pumps being used, besides flat rods and V-bobs for pumping below the tenth level, which made a somewhat complicated system, and one that created the danger of the lower levels of the mine being flooded in case of a very wet winter making an extra amount of surface water to be handled. The new engine will be used in raising the water from the bottom of the mine to the tank on the 800 level, and from that point (where the surface drainage and that from the old Eureka workings is caught) will be raised to the surface by the old engine. This will give two independent pumping systems, and there will be no such strain upon the engines as to create the danger of their capacity being overtaxed.

The new engine, of which a description is given below, taken from the San Francisco MINING AND SCIENTIFIC PRESS, was manufactured at the Union Iron Works (Prescott, Scott & Co.) of that city, under the supervision of Edward Coleman, President and Superintendent of the Idaho Co. To prepare for this engine, the ground was broken last October, the excavation being made 28 ft. down to solid rock, and on this a foundation of granite, laid in Portland cement. This foundation is 63 ft. in length, 28 ft. in depth, and of a varying width of from 16 ft. to 33 ft., and firmly bolted together by 12,000 lbs. of 2¼-inch iron bolts. The cap stones on which the engine rests, amounting to 260 cubic feet, are dressed granite blocks, from the Penryn quarries. The building erected to enclose the engine as now in place is 47 ft. span by 44 ft. in length, 20-ft. posts, and supported by a truss roof. * * * *

The designs for these new improvements at the Idaho were drawn by J. V. Pitchford, master mechanic, who has superintended the erection of the same at the mine, and who is recognized as very competent, having acted in a similar capacity for several of the mining companies on the Comstock.

The expense of these new pumping works will be about $31,000, and it is expected that they will be adequate for whatever depth the mine may be worked in the future.

News in Brief.

NEW pumping works costing $31,000, have been put up in the Idaho mine in Grass Valley.

NEW YORK has never been more crowded than it is this winter. The hotel-keepers are making fortunes.

THE Northern Pacific Railroad Co. will, in the spring, have one or more light-draft powerful steamers on the Yellowstone.

THE cold weather is causing great suffering among cattle running at large in the valleys in Nevada and Idaho. A number of cattle died of thirst, the streams being all frozen.

IT is reported that the Madrone mineral springs, situated a few miles northeast of Gilroy, will be purchased by a company at Oakland for $8,000, and that $12,000 more will be spent for improvements.

HERBERT SPENCER'S meditated journey to America is now definitely fixed, he says, for August next, and he intends to be absent three months. He will visit Canada and also possibly California. He has refused all proposals to lecture, his design being solely to see the country and the people, without any ulterior object.

REPORTS from all parts of the coast of the unprecedented coldness of the weather continue to reach us. In many of the northern counties of the State the miners have been compelled to stop work, because all the water had formed to ice. Stock, cattle and sheep men also say that the cold weather has caused large losses among their stock.

MRS. C. D. SMITH, of Visalia, was scalded to death last week. She was bathing in a tub near the stove on which was sitting a kettle half-filled with boiling water. On coming from the bath she became dizzy, and to save herself from falling, clutched the boiler and pulled it from the stove, the contents completely covering her body.

INFLUX OF CHINESE.—So far this month 3,387 Chinese immigrants have arrived in this port. The *Bothwell Castle* brought 1,029 on the 2d, the *City of Rio de Janeiro* 691 on the 6th, the *Gaelic* 890 on the 9th and *Suez* 777 on the 13 h. This is an increase of 1,185 over the total arrivals during the month of January.

THERE is no abatement of the disasters that have overtaken the planters of the Mississippi valley caused by the overflow of the river between Memphis and Vicksburg. Inch by inch the river has been encroaching upon them, until now there is but a dreary watery waste, extending fully 15 miles in and from either bank.

GEN. SKOBELOFF refuses to disclaim one jot or tittle of the anti-German sentiments to which he has given utterance in his famous speech. "Yes, I did say that Germany is a common enemy, and I repeat it. I believe that safety lies in the union of the Slavs with France. The European balance of power must be re-established, or there will soon be only one power—Germany."

FORTY cords of blue gum wood have been shipped to San Quentin by A. R. Hall, of Haywards, to be worked up into chairs at the State Prison factory. This is the first experiment in this direction, and its results are awaited with much interest in Alameda county, where the gum tree grows luxuriantly in all kinds of soil. The wood was cut in the Stratton grove, planted in 1869 and 1870.

SECRETARY HUNT has received a letter from Hoffman, at St. Petersburg, respecting the relief expedition in search of the Jeannette survivors, stating that the reason why Engineer Melville was placed in command of the party was that Lieutenant Danenhower was physically unable to perform the duties of the office, as, in addition to having lost his eyesight, his terrible affliction had caused temporary aberration of mind. It is now believed Danenhower has fully recovered his reason, and his general health, as well as that of the other members of his party, is being gradually repaired.

THE Girard Co., at Tombstone, have started up their mills. Theirs is the only mill in that district working close to the mines. This makes a saving of at least $3 a ton. If this proves a success, other mills will be put up near the mines.

PERSONS receiving a sample copy of the MINING AND SCIENTIFIC PRESS *with this notice marked*, are requested to examine the merits of the same, and consider fairly its claims for support, and if consistent, subscribe for the paper through the P. M. or agent delivering it, or otherwise. We shall send it, on trial, at the rate of $4 per annum for any period the reader may wish. Please notice our terms elsewhere, and if desired, send for further samples and information. Those who can circulate this No. further to our advantage are invited to do so.

A TURNED LEAF will point out the article supposed to be of special interest to persons receiving sample copies of this paper.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

BOUND VOLUMES OF THE PRESS.—We have a few sets of the back files of the MINING AND SCIENTIFIC PRESS which we will sell for $3 per (half-yearly) volume. In cloth and leather binding, $5. These volumes, complete, are scarce and valuable for future reference and library use.

CORRESPONDENCE on mining and other subjects represented by this journal is solicited from all reliable sources. Send us information, early and often, if ever so brief.

BY TELEPHONE.—Subscribers, advertisers and other patrons of this office can address orders, or make appointments with the proprietors or agents by telephone, as we are connected with the central system in San Francisco.

THE State Mining Bureau, No. 212 Sutter street, is open to the public from 10 o'clock A. M., to 5 o'clock P. M. daily, (Sundays excepted). Henry G. Hanks, State Mineralogist.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

G. W. MCGREW—Santa Clara county.
M. P. OWEN—Santa Cruz county.
B. W. CROWELL.
J. W. A. WRIGHT—Merced, Tulare and Kern counties.
JARED C. HOAG—California.

A large cylinder Hoe printing press, for country newspaper work, can be bought cheap by addressing
Press, Box 2361, S. F.

Sewing Machines.

Several first-class styles, good as new, will be sold at a bargain. Call on or address H. F. D., at this office.

Mining and Scientific Press.

THE MINING AND SCIENTIFIC PRESS is the leading mining journal in America, and enjoys a larger circulation among the more intelligent operators and workers in the gold fields of the world.

Established in 1860, it has firmly maintained its position as a reliable, progressive journal. The information given in its columns has saved millions of dollars to the practical miners, metallurgists, mill men, mine and shareholders on the Western side of our continent.

Among its contributors are the ablest and most experienced mining engineers, superintendents and practical miners in this country.

The PRESS gives a condensed summary of Mining News from the most important mining districts of the country.

New processes and methods of mining are described in its weekly issues. New mining machinery and improvements are frequently illustrated and explained in a manner to be of great value to all interested in mining.

As a scientific and mechanical representative of the Pacific coast it is decidedly popular, and a standard journal with the most thrifty industrial people of the Pacific States and Territories. Its authority is of the highest order, and its usefulness in its special sphere unrivalled.

Every public library, mining engineer, metallurgist, mining operator and intelligent mechanic and manufacturer, will find profit by its reading.

Subscription, $4 a year in advance. Sample copies postpaid, 10 cents.

AMERICAN MACHINE AND MODEL WORKS.

All kinds of Light Iron and Wood Work, including Patterns, Gear Cutting, Planing, Engine, Musical Instruments and other repairing. Dies, Taps, Reamers, etc., a specialty.
HEALD & BANKS, Proprietors.

WANTED.

A Mining Manager for a Quartz Gold Mine in Nova Scotia. He must be thoroughly posted in mining, milling, etc., and of undoubted reliability. The best references required. Apply by letter stating age, particulars and length of practical experience, references and salary to "Quartz," care of Railroad Gazette, No. 73 Broadway, N. Y.

HERCULES SLAYING THE GIANTS.

HERCULES POWDER

Derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

No. 1 (XX) is the Strongest Explosive Known.
No. 2 is superior to any powder of that grade

PATENTED IN THE UNITED STATES PATENT OFFICE.

THE CALIFORNIA POWDER WORKS,

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and HERCULES Powder

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

Office, No. 230 California Street, - - - - San Francisco, Cal

Tubbs Hotel,

OAKLAND, CALIFORNIA.

An elegant family residence in charming grounds. Two hundred rooms. Near steam and street cars. Forty minutes to or from San Francisco. Trains every half hour. Five-cent fare. Table d'Hote or Restaurant. Splendid suites of sunny apartments or single rooms with or without bathrooms. The most HEALTHY and agreeable location on the Pacific Coast. Mean yearly temperature 55° Sun unobscured from March to November. A HOME for tourist or invalid. Good cuisine under a celebrated Chef. Prices more reasonable than any hotel of its character in California. Livery stable, laundry, billiard room, telegraphic communication, etc., in connection with the hotel. Special terms made. All applications answered.

SHELDON I. KELLOGG, Jr., Prop'r

Scientific, Mining and Other Valuable Books.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS Office, S. F.

BY GUIDO KUSTEL.

MINING ENGINEER AND METALLURGIST.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequaled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery etc., which alone are of the greatest value. PRICE, $7.50

ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver. 1880.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 156 pages, embracing illustrations of furnaces, suplements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.

Price, $3.00 coin, postage free.

Rare Cabinet of Minerals.

A physician who has long resided in the mines and other parts of California, and gathered a large and valuable collection of minerals and other specimens, offers the same for sale at a bargain. Address "Cabinet," box 2361, San Francisco.

Send for New Illustrated Catalogue.

MINING AND SCIENTIFIC PRESS.

An Illustrated Journal of Mining, Popular Science and General News.

BY DEWEY & CO., Publishers.

SAN FRANCISCO, SATURDAY, MARCH 4, 1882.

VOLUME XLIV Number 9.

New Vertical Air Compressor.

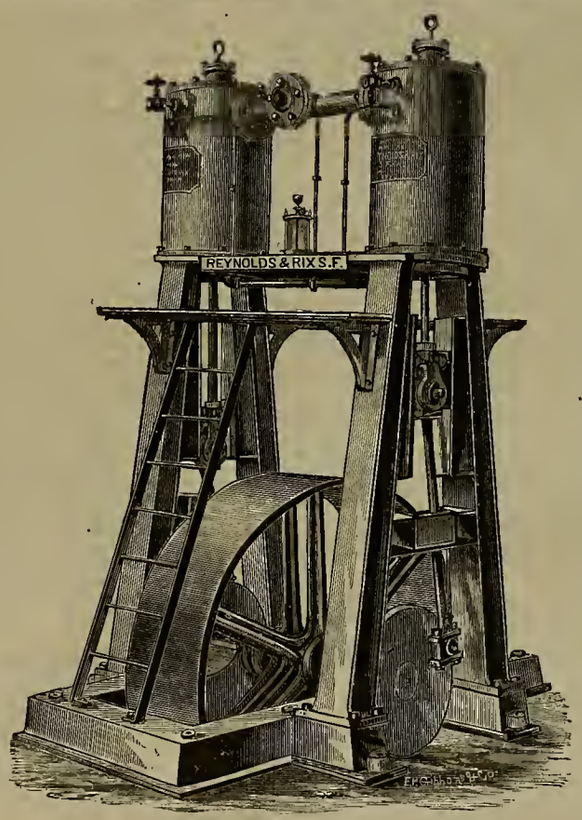
The compreseor of whioh we ehow a cnt of the style for water power on thie page, is one patented hy Edward A. Rix, through the MINING AND SCIENTIFIC PRESS Patent Agency, Dec. 7, 1880, and is mannfactured aud sold hy Meesrs. Reynolds & Rix, dealere in National rock drills, and general mining machinery. The compreesor, as ehown hy the engraving, is for water power, or to he driven hy any helt power. It is arranged with two vertioal cylinders supported on iron frames, which are eecnrely faetened onto an iron hed-plate. Theee framee are joined hoth hy a diaphragm and the platform platee, ae well ae the eduction pipes, so that they are rigidly faetened together ae well ae to the hed-plate. A etraight ehaft liee aoross the hed-platee, rnnniog in large hoxee and having large turned disks on the ende for oraoke. The connecting rode are long, thne making eaey motion on the elidee; and eteel piston rode, together with large pieton surface, make thie compreseor light running and very tight.

The peculiaritiee of the invention are in the general mode of arrangement, ae well ee speoially a new kind of sefety diecharge head, which admite of complete discharge ae well as rendering accidents to heade imposeihle ehould valvee or other enhstance get hy any chance into the cylindere. The inlet valvee are ecrewed into the pieton. All valves and jointe can he reached in a moment, and the machine ie eepecially deeigned to he a compreseor that an ordinary mechanic can keep in good rnnning order.

To each compreseor ie attached a pneumatic lnhricator, which is one of the advantages connected with ueing this machine. This lnhricator insnree a poeitive feed of oil into the cylindere, therehy rendering accident to cylindere hy cnt-ting an impoecihility.

The mannfactnrere eay: "Water ie not injected into the cylinders, consequently there ie no trouble either with complicated mechanieme connected with ench an arrangement, or difficulty with damp air and watcr, forced into enginee or drills nndergronnd hy euch machinee. A eimple water-jacket eurrounde each cylinder, which aheorhe a great proportion of the heat consequent upon compression."

Messre. Reynolde and Rix make varione eizes of these machinee and have a numher in eucceeefnl operation. Among theee may he mentioned: Two at Mullen Paee tunnel, N. P. R. R, Montana; two at Spring Valley H. G. M. Co's worke, Cherokee; one at Sierra Bnttee mine, and one at Amador Pacific mine, Plymouth. Partiee desiring to know more ahont theee machinea can eee them on exhihition at the ealeeroome of Meeers. Reynolde & Rix, 49 Fremont etreet, in thia oity.



THE RIX NEW VERTICAL AIR COMPRESSOR.

Exploder for Firing Blasts.

Alexander Watson, of thie city, hae patented, through the MINING AND SCIENTIFIC PRESS Patent Agency, a new appliance for exploding hlaete.

This novel method of firing explooives ie adapted epecially for that clase known as high explooivee, of whioh nitro-glycerine and ite oomponnde are repreeentatives. It ooneists in the employment of a metallic cylinder having in ite lower part an anvil to receive an explooive cap, while ahove it a pieton or hammer slidee within the cylinder, being actuated hy a atont epring. The hammer has a etem or epindle, the upper end of which ie secured at the upper part of the cylinder when the hammer ie drawn np, hy any solder or composition which may he acted upon hy quickeilver. A cap acrewe down over this joint. The oap haa a drop of quioksilver placed within it and the device ie kept bottom up until needed eo that the quickeilver may not touoh the joint.

When it ia to he ueed, the cap heing placed on the nipple or anvil, the apparatne ie revereed ao that the qnicksilver may rest upon the joint, when it will attack it and looeen it, ao that the hammer may fall and explode the cap and the charge into which the cylinder ie introduced. The time ia regulated hy the amonnt of solder or cement, eo that it aote like a time fuee or mechanism.

The time of the explooion ie determined hy the amonnt of the material nsed ae a solder, and thie may he regulated eo that the explooion will occnr at the exact moment desired.

The Debris Case.

The argnment in the dehrie oaee hefore Judge Temple wae commenced at Sacramento thie week. The Court meete in the Snpreme Court room, hy coneent. George Cadwalader claimed theee pointe ae vital: First—Hydranlio mining is the exerciee of a right which prevents othere enjoying their righte, a uee of property whioh prevents othere enjoying their property; it ie, therefore, a nnieance. Second—It thne interferee with and dieturhe large numhere of citizens; it ie, therefore, a nuieance. Third—there can he no prescriptive right gained in the maintenance of a nuisance. Fourth—The Statute of Limitatione will not run aa againet a nuisanoe. Fifth—A pnhlic nnieance may he and ehould he ahated. Sixth—It ie no anewer to a charge of nuieance to say it aleo producee henefits. Seventh—The United Statee gnarantees the free uae of the navigahle etreams to the people. Eighth—The State cannot, hy law, or neglect, or permieeion, conoent to any ohstruction to enoh etreame. Hydraulic mining doee ohstruct the etreame, and prevente their free use and eojoyment. Ninth—Therefore, it ie a puhlic nuisance and ahould he ahated. Tenth—Hydraulic mining proper did not hegin till 1865, and it has not gone on without proteet. Custom is no defence, if the custom he a nuisance. Eleventh—Hydranlic mining, it is proven, ie not profitahle, hnt agriculture is profitahle, and the former ehonld not he weighted againet the latter aa heing a profitahle industry. Twelfth—A court of equity will interfere to prevent the continnance of a nuieance, and will direct and compel hydranlic miners to ceaee the depoeition of tailinge in the etreame or canyons, or ravines trihutary thereto.

The Microscopical Society.

The meeting of the San Francisco Microecopioal Society last evening was the firet under the new officere, who were choeen at the previone meeting as followe: Preeident, W. Ashhurner; Vice-Preeident, Wm. Norrie; Recording Sec'y, E. J. Wickeon; Corresponding Sec'y, C. W. Benke; Treas., Arthnr W. Hickox.

Dr. Harkneee preeented a hottle of "red enow" which he gathered last June on the Waeatch mountaine. The red enow was found on the north side of a epur which rose ahout 10,000 ft. ahove the eea level. When freeh, the snow hae the appearence of heing drenched with hlood, ae though eome large animal had heen killed. The "red snow" is caneed hy the preeence of a one-celled plant called *protococcus nivalis*, which reprodnces iteelf by euhdivision; that ie, the cell divides iteelf into eeveral new cells. Thie ie done with great rapidity, and a few celle lodged in the enow, under favorahle conditione, eoon will give it the appearance called "red enow." It wae remarked that the phenomenon of red enow had heen ohserved from the earliest timee, ae Arietotle has a paesage which ie thought to refer to it. The euhject was, however, lost sight of until hronght np hy the inveetigations of Saussure, who found it on the Alpe in 1760. He made chemical teets which ehowed him that the red color was due to the presence of vegetahle matter, which he euppoeed might be the pollen of eome plant. In 1819 an Arctic expedition under Captain Roee, hrought eome specimene from the cliffs around Baffin'e hay, and they were examined hy eminent hotaniete, eome of whom mietook the nature of the plant, and there wae long diecusoion ae to its proper classification, eome holding it to he a fungns, eome a lichen; hut it wae finally eet at reet ae one of the unicellular algæ. It is of intereet also thet eome of the early examinere prononnced the color due to animalculee, hut this wae dieproved. Dr. Harkneee said that during his last vieit to Eogland he saw the original hottle of epecimene hrought from the Arctic more than 60 yeare hefore, and in which the *protococcus* could etill he eeen with the microecope.

Henry G. Hanks, State Mineralogiet, made eome remerke concerniog the volatilization of gold, reading a communication on the euhject from E. W. Morley, of Hudeon, O. He exhihited two elidee eent by Mr. Morley, eaoh of a epecimen of the metallic glohnles, said to he gold, from the roof of the Mint at Philadelphie. Theee were examined with a two-third objective, and Prof. Hanke atated that his examination and treatment of them with acid showed conclusively that gold would hecome volatilized, and no douht pace off in the fumes from the retort.

SINCE January 1, 1881, there have arrived in San Francisco hy steamer from Hongkong 23,401 Chinese. The number each month wae ae followe: January, 553; February, 300; March, 993; April, 595; May, 2,329; June, 3,057; July, 2,072; Angust, 1,818; September, 918; October, 915; November, 2,716; December, 2,308; Jannary, 1882, 1,359; February, 3,468. In the eame time the departures of Chinese from our ehoree for their homee have heen about 8,000. This shows a net increase of this nndeeirahle population amounting to 16,000 during the time mentioned. The arrivals during the laet four monthe have averaged ahout 2,500 a month. The number in February increaeed over 70% npon thie average, although the month ie the ehorteet in the year.

THE water of the White Mountain Water Co. hegan rnnning through its pipes into Candelaria Saturday afternoon. The people are juhilant at the aeenred anceese of this gigantic enterpriee. Ite influence will he very materialy felt in Columhue mining district, the near advent of the Carson and Colorado railway aeeisting euch feeling in a great measure.

GOLD quartz haa heen struck in the Ontario claim at Stampede Gap.

THE Silver Cave mine, of Doe Cahezae, still continuee to enrpriee all who vieit the dietrict. Parties juet in from the district tell the Arizona *Star* that it ie the higgeet gold mine ever diecovered on the continent. The grade is high, and ore easily reduced.

BULLION shipmente from the Starr-Grove mine at Battle Mountain, Nevada, have been renewed.

PUMP ROD COUNTER-BALANCE.—The Union ehaft, on the Cometock, lately received a pumphoh weighing 16 tone. It will carry, when in place, 30 tona ae a counter-halance to the pumprod. The oombined weight of the halance in the eeven hohe at the Union ehaft ie 210 tone. The weight of the pnmp-rod and water eet in motion hy every atroke of the engine, is eomething over 400 tone, run at a epeed of from 3 to 10 etrokee per minnte. Four hundred tons per stroke, 2,800 tona per minute, 168,000 per hour, and 4,032,000 tone every 24 houre, ie the weight moved hy the pumping engine at the Union ehaft.

THE Richmond Con. mining Co. has just paid a quarterly dividend of $2.50 per share at London, aggregating $135,000, and making a total to date of $3,637,600, equal to $67.87½ per share. The mine adjoine the Eureka Con., which hae not paid a dividend eince laet year, and which only produced $60,000 in January.

THE January product of the Tombstone district, Arizona, is reported at $375,000, of which $121,800 ie credited to the Contention Con., $110,000 to the Tomhetone and $100,000 to the Grand Central. The Tomhetone *Nugget* of Feh. 4th eaya that the Grand Central has paid $650,000 inside of a year.

Water Jacket Smelting Furnaces.

We have illustrated and described in these columns the water jacket furnaces, both for galena and copper ores, of the types designed and manufactured in this city by Rankin, Brayton & Co., of the Pacific Iron Works. Upwards of 50 of this style of furnace are now at work in various camps on this coast with satisfactory results. In California, Idaho, New Mexico and Arizona the water jacket furnace, made ready to set up without the aid of masonry or brick work of any kind, finds ready acceptance. As compared with the old style of furnace and the relative efficiency, the cost is small. It may interest some to know from some one who has used the galena smelters how they work, and we append a statement from the Superintendent of the Castle Dome Smelting Works:

MELROSE, CAL., Feb. 18, 1882.

Messrs. Rankin, Brayton & Co., Pacific Iron Works, San Francisco, Cal.—GENTLEMEN: In reply to your application for a statement of the working of our furnaces, would say that we have two of your 40-ton galena smelters in our works that have been running most of the time for the past two years. With ordinary care I have no difficulty in keeping them in condition for constant service. The patent circulating plates, recently introduced into your water jackets, I regard as the most important improvement ever made in water jacket furnaces, and worth more than the entire cost of an ordinary jacket.

There is no question but that a jacket, for either galena or copper ores, with this improvement, will last two or three times as long as without it, besides lessening the liability to injury and the consequent expense and loss of time for repairs. Since the adoption of this improvement, I have had no trouble whatever with my jackets. The circulation of the water is so rapid that the inner surfaces of the plates are kept scoured and entirely free from any incrustation, and it seems to afford perfect protection from the effects of mineralized water, and from the overheating and burning out so common in all other jackets. Your style of sectional water jackets has many and obvious advantages over all other forms. The distribution of the blast and the angle of the tuyeres are such as are calculated to secure perfect combustion and the greatest economy of fuel.

With a long and varied experience in smelting ores from a wide range of mineral country, I unhesitatingly give your furnaces the preference over any I have ever seen. The machinery comprising the smelting plants furnished by your firm I regard as admirably suited to that purpose—complete in detail and adapted to all the requirements of practical work. The improvements you have made in this class of mechinery are recognized as of great value to the mining interests of the country, and make smelting, under ordinary conditions, the cheapest form of reduction for any ores that can be worked by this process. Yours truly,

W. P. MILLER, Supt.

Wealth Produced by Hydraulic Mines.

L. L. Robinson, Vice-President of the Hydraulic Miners' Association, testified in the Gold Run case that the stockholders in the hydraulic mines have paid out thus far the enormous sum of $7,600,000, and have received in dividends but the paltry sum of $1,350,000, making a loss of $6,250,000. Where, then, is "the wealth produced by the hydraulic mines?"—*Sacramento Bee.*

The *Bee* is very funny when it argues about hydraulic mines. It talks like the stockholders of those mines had dumped $7,600,000 into a hole in the ground and covered it up. On the contrary the truth is that that same $7,600,000 is now in existence and is circulating around the world, doing good to commerce and manufacturing. The money was paid by those holders of hydraulic mines to workingmen, and the money went to support happy families. Then, while the $7,600,000 are still in the world, the works that that money put in operation have brought into circulation $1,350,000 as dividends, and about as much more for running expenses. We have then the $7,600,000 still in the world, and that operated to bring, say $2,700,000 worth of coin into the world. That is wealth produced by the hydraulic mines. The world is getting more benefit than the owners have yet realized from that class of mines, but still the wealth produced will buy a great many potatoes.—*Nevada Transcript.*

WARNING TO WHEAT EATERS.—"How is it," asked a reporter of a Stockton paper of a prominent wheat buyer, "that you wheat men always spit out the grain you sample?" "That is easy enough to explain," said the man of cereal proclivities. "Do you know that many a man has ruined his constitution, and in lots of instances consumption has been brought on by acquiring the habit of eating wheat? The reason is this, the husk of the wheat somehow or other finds its way into or affects the lungs. In Mark Lane it is the custom to fine any man found eating wheat one shilling." This will be received as news by the general public.—*Sac. Bee.*

THE enormous quantity of $1,000,000 worth of blasting powder was used in Colorado during the past year.

White Mountain District.

A Little-Known Region in Inyo County.

A correspondent of the Inyo *Independent*, writing from the above locality, says: If you can find space in your valuable paper, I desire to lay before your many readers a few facts in regard to a mineral zone or belt, of which little, if anything, is known among the mining men of the Pacific coast. I do not make pretention of being a mining expert or newspaper writer, but simply state what I know to be facts, and what anyone can see by visiting the country. Many of your readers are engaged, more or less, in mines and working minerals, and ores of every kind in which this county abounds. But such interests in this county are only in their infancy. There is more precious metal to be found on the surface in this county than any other to be found on this side of the Rocky mountains. If the White mountains could be placed just as they are to-day in New Mexico or in Arizona, there would be a general stampede for the county. The newspapers would have a boom, and millions of money would be made in less than two years. Music sounds the best afar off, when heard.

Now, about this mineral zone or belt of argentiferous galena ore. It is situated on the eastern slope of the White mountains, about four miles southeast of the summit, facing Deep Spring valley and about seven miles west, up Wyman creek; Crooked creek at the north, and Birch creek south. It is about five miles in length, and three-fourths miles wide. The formation is lime and slate. We will start above the old stone cabin on Crooked creek and follow the main mother ledge of this belt. Where we strike the outcrop of this mammoth lode is about one-fourth mile south of the creek, on a small round hill of solid formation. We find a shaft sunk on the vein some 14 or 15 ft., and from 20 to 30 tons of first-class smelting ore on the dump, chlorides, carbonates and galena; vein four ft. between walls; the ledge crops out about 300 ft. Here we cross a dry ravine and shortly we find another shaft down 42 ft., and about 40 to 50 tons of ore on the dump. The vein is about 2½ ft., of splendid ore. I was told the average of this ore, as it comes from the bottom of the shaft, assays $89.58 in silver, $21.30 in gold, and 48% lead. This is also located in a permanent hill, and has slate foot and lime hanging walls.

This mine is situated on the north side of Coalburner's canyon. About 200 yards above, west and up this canyon, is a valuable spring of fine water, which runs some six inches in the dryest season. I was also told that this spring was claimed by the mine owners. This I consider a fine property. Here we leave Coalburner's canyon and go south, following the main belt to Wyman creek. On our way we find three locations that look well, all showing more or less mineral, and of good grade. On this main fissure vein, which extends through this belt from Wyman creek to Birch creek south, there are 35 locations made, all showing veins from 12 inches of solid metal up to 6 ft. of fine chlorides, carbonates and galena ores. To describe this section, and why this country has been kept in the background, is what I propose to show to your readers. To do so in this letter will take up too much space. Next week I will give you a slight idea of the country from Wyman creek to Deer creek, and from there to Birch, where all of the most valuable mines are situated.

TOHONGO MINES.—Capt. L. Haight, Superintendent of the Tohongo mines made a pleasant call recently at the *Commercial* office. He reports the mines in his district in a prosperous condition, and the mine he is superintending having a four-foot vein of ore that averages $25 per ton and has yielded $40 per ton by the arastra reduction, and some assays have run as high as $200 per ton. The company is composed of San Francisco capitalists, and over $20,000 have been expended in prospecting and on the mill, which is Haight's improved Chile mill and is equal to about 10 stamps. In about a month the mill will be in running order and then we may expect a mining boom in Los Angeles county. The mines of this company are situated about 20 miles southwest of Ravenna Station on the S. P. R. R. and in the north side of the Sierra Madre mountains near the headwaters of the little Tujunga creek. A good wagon road has been made to these mines mostly over the mountains. Captain Haight thinks a good wagon road could be constructed from Los Angeles to the mines, with 30 miles of smooth track and but 10 of mountain road. This road would open up a large mining camp to the trade of this city, and could be made at a small expense. There are other mines in the vicinity that would be tributary to this road and make a lively trade with this city.—*Los Angeles Commercial.*

LUDWIG & CARTER COPPER MINE.—The smelter is now turning out a little over 100 lbs. of copper every half hour, which, for its size, is considered pretty good work. A large iron water tank has arrived and will take the place of the smaller one heretofore used. Mr. Jones, the smelter, has proven his water-jacket invention a success. It does away with the use of fire-bricks and obviates the necessity of stoppages every few days to replace them. Last week a car-load of copper bullion was shipped to San Francisco. Copper having advanced to 23 cents, the owners of the Ludwig & Carter ought to realize a handsome fortune from their mine.—*Esmeralda Herald.*

What Developments on Silver Hill Show.

The developments on Silver Hill in the Cortez, Utah and Centennial mines, which are located towards the lower portion of the northwest side of the hill, goes to prove beyond a doubt that there are very large bodies of ore in the larger veins higher up on the hill. The Cortez's lower tunnel taps their ledge over four hundred ft. below the surface, where they find it stronger than on any other level in the mine, and carrying as rich ore as at any other point, which gives them four hundred ft. to stope between their tunnel level and surface. Just imagine how much ore there must be in the Silver Hill Consolidated, or the old Esmeralda, which is the highest ledge in the district between the surface and the level of the Cortez tunnel, the difference in elevation being about 800 ft., and the ore in the Esmeralda from the top of the ledge, which stands 70 ft. above the surface of the summit of Silver Hill, as deep down as the chute has been prospected assaye for a thickness of three or four ft. nearly $500 per ton. Should the ore continue down, which we have every reason to believe it will, as the vein is nearly ten times the thickness of the Cortez on the surface and stands up almost vertical, while the latter dips at about sixty degrees, what an immense thing it will be. And between the Cortez and Esmeralda there ie the Silver Hill Consolidated, which was formerly the Excelsior, with a very strong ledge having one of the best hanging walls in the district, and very fine looking ore in the ledge, the Seminole and many others which look very favorable as far as work has been prosecuted; and if the theory advanced by W. P. McIntosh in his communication in this issue is correct, and we have no reason to doubt it, as he has given a great deal of attention to the study of the formation of this district for the past four years, Silver Hill can turn out enough money to pay the national debt.—*Esmeralda Herald.*

The Sandias—Past and Present.

The Sandia mountains are dotted with ruins of ancient smeltere of a kind that are not in use anywhere at the present day. The native New Mexican or Spanish people do not appear to have acquired the mode of erecting them from the Indians. Even the Pueblo of to-day seems to be ignorant of the manner of their construction. They were cheap and simple, but they answered the purpose admirably. But in no instance has any indication of the existence of a stamp-mill been found in the Sandias. This would show that ancient mining was not restricted to the working of free gold, and that the extraction of gold from smelting ore was understood. But it is undeniable that discoveries in the modes of obtaining gold from combinations of ores have recently been made that could never have been known to the ancients, and this is proven by the fact that much of the slag now found near these old smelters contains gold in considerable quantities. Yet the records, histories and traditions agree that gold was obtained in fabulous amounts. With modern appliances and new and cheap methods, the yield should now be much greater. Gold ore in whatever shape can now be cheaply treated and not an atom be lost. When one takes into consideration the great bulk of gold taken out of the Sandias by the Indians in their crude way, he must be convinced of the wonderful richness of these mountains. There is every reason to believe that the Sandias will eventually be regarded as the greatest of all New Mexican mining districts.—*Bernalillo News.*

Another Montana Boom.

The Bismarck *Tribune* of the 20th ult. has a flaming account of Maidenville and the mines around Fort Maginnie. Its information probably came from a prospector who "got a job" the day he "struck town." If he had remained without work 48 hours he would doubtless have given the town a black eye, after the manner of some recent Butte experts.

The *Tribune* says: The chances are becoming numerous that the new silver mining region in the vicinity of Fort Maginnis, M. T., will attract a big stampede in the spring. Five miners and prospectors, the discoverers and early pioneers of that camp, who have been East, arrived here last evening on their return. During a conversation with one of the number, we learned that the new mines are located about six miles from Maginnis, in the Judith basin, in the Snowy mountains, between the Yellowstone and Missouri rivers.

The first silver ore was struck last May, and now there are over 2,000 inhabitants in that section, many of whom are from the Black Hills. The largest town there is called Maidenville. It is the opinion of our informant that the mines on this belt will prove the richest ever discovered in Montana.—*Inter-Mountain.*

BORACIC ACID WORKS.—R. E. Doran's teams are now engaged on a contract to haul 100 tons of "cotton balls" from the old Columbus borax marsh to the Phœnix chemical works at Columbus, owned by Wm. M. Purdy. There are a number of Chinamen employed at the marsh gathering the borax "cotton balls." The work, though small, are a decided success, preparing the raw material to a fineness of 95% for shipment.—*Esmeralda Herald.*

ARIZONA, it is estimated, will output 15,000,000 lbs. of copper during the present year.

Richness of Cochise County, Arizona.

The Tombstone *Epitaph* says: In looking over the mining field, not alone of Tombstone, but the entire county, we see nothing but the most hopeful signs for the future. At home, new claims are being brought to a state upon the border line between prospects and mines, where, by the judicious investment of comparatively small capital they would, in most cases, become paying properties. Bisbee, the great copper camp of Arizona, is in a similar condition. There are a score or more of the most inviting copper locations in that camp that give unmistakable indications of large deposits of ore similar in nature to that of the celebrated Copper Queen mine. In the Huachucas, developments are steadily progressing upon several properties that give strong evidence of soon becoming large producers of both copper and silver. Reports from the newly discovered mines in Winchester district are most hopeful. The property purchased by H. Solomon and George Hearst is opening out quite as rich as they expected when they made the purchase.

Other claims in the same vicinity are also showing rich ore, which gives the owners faith that they are upon the verge of bonanzas equal to anything in the Territory. Dos Cabezas is also looming into unwonted prominence, and we hear of sales being negotiated at remunerative prices to the locators. This is the gold district, par excellence, of Arizona. The ledges are described as large and well defined, with the gold evenly disseminated throughout the vein matter. It is believed by those who have cast their lot in that locality that the day is not distant when Dos Cabezas will take rank with the most favored districts in the land. We also hear good news from the mines in the Chiricahua mountains—at Galeyville and Ayre camp. The Texas smelter has of late been doing good work, and Col. Clute feels perfectly satisfied that when their smelter shall be in operation he will turn out a continuous stream of bullion, to gladden the hearts of the owners.

Returning toward home again, we strike the mines in the Dragoons, which show remarkably well for the work done upon them. In the Turquois portion of the Dragoons this is particularly the case. Upon the western slope there is a force of men taking out ore from the Silver Cloud and also from the Royal Arch mines, which is of high grade.

That Cochise county is one of the richest pieces of territory within the borders of the United States is a perfectly safe statement to make, and that were one-half its resources developed we would be reminded of the palmy days of Washoe, when one-half the people were crazy with the argentiferous wealth of the Comstock.

Heat in Silver Mines.

If there is to be found anywhere in the world, says the Virginia *Enterprise*, a set of human salamandere, we may claim the credit of having them on the Comstock. What would scorch men who live wholly on the surface, chills the miners who are inured to the lower levels. A miner who has been for some months past working in one of the hottest sections of the Comstock, a day or two since gave an *Enterprise* reporter his experience of the heat which miners are often called upon to encounter. He says that in working at points where the thermometer marks a temperature of 115 to 120 degrees great thirst is experienced. No ice-water is too cold to be swallowed with a relish. Men go to the water-barrel, in which huge chunks of ice are floating about, and will take their picks and chop up the ice in order that the water may be rendered cooler by being filled with small fragments. Often this does not satisfy them, and they chew up and swallow lumps of ice. The natural temperature of the human body is about 97°, Fahrenheit. Therefore, when a man remains in a hot place for an hour, or even half an hour, his blood and even his whole body becomes heated to a temperature of 115°, 120°, or whatever the temperature of the place where he is at work may be. It is then that the miners begin to pour down ice-water and to eat ice. The strangest thing about the business is that it does not hurt any of the men. Often they swallow such quantities of ice-water that their stomachs will not retain it, and in vomiting it up it will feel cold in their mouths and against their teeth. All they do on such occasions is to swallow some more, but more cautiously.

THE earliest attempt to obtain light by incandescence in a vacuum was made by King in 1843, who applied continuous metallic and carbon conductors and heated them by the electric current in a Torricellian vacuum. He was followed, in 1848, by Staite, who used an iridium or an iridium and platinum wire, and enveloped the holder in glass or some other non-conductor. In 1872 Konn employed graphite and rendered it incandescent in an atmosphere of nitrogen, in which there was no wasting away of the carbon. The same principles have been followed, but with greater promise of success, in the more recent attempts of Edison, Maxim and Swan at producing illumination by means of incandescence.

INCREASED mining excitement is observable all through the New Mexican mining camps, and mining machinery and supplies are crowding all the thoroughfares leading to them.

MECHANICAL PROGRESS.

The Circular Saw.

In Europe the circular saws are made considerably thinner than in the United States. Much more skill is necessary in hotb the manufacture and use of suob saws than in the tool as employed in thia country. Our mechanics, however, are sufficiently skillful to uso the thinner saw whenever they find economy in so doing, or whenever the manufacturers meet with a demand for the change. The scarcity of timber in Europe is an objection to the greater wastage attendant upon the uso of the thiok saw. The *Northwestern Miller* says that hitherto the thick circular has proved a rapid and cheap servant, giving a maximum duty with a minimum of cost, both for repairs and attendant labor, in the past days of a bountiful supply and corresponding cheapness of product, and a mere change of saw thickness hardly seems sufficient cause to seriously impair its position. It is to be remembered, however, that considerable difficulty has been encountered by those who, foreseeing the demand for thin circulars, have experimented in their manufacture.

The fact seems to be that in every part of the manufacture greater skill is requisite. Thus the straightening, the regulation of the degree of tension, the balancing and the hanging, require more careful manipulation. In the use the speed must be kept more regular, the belt must be kept more tant, heating must be more carefully avoided, and the set and truth of the teeth more rigidly maintained. In addition to these requirements, there are, however, some that pertain to the machine itself; thus, the spindle and collars must be more rigid and free from vibration, lost motion or play in the parts, while all the adjustments will require to be more accurately made. All these requirements, however, will be successfully met and supplied just as soon as the saw user calls upon the manufacturer and the mechanic to supply them.

LINKS.—To close a quadrant or link that has sprung or opened in hardening, clamp it with bolts and plates, placing the die in the slot to support any part which does not require to be closed. To open the slot of a quadrant or link that has closed in being hardened, take two keys having an equal amount of taper upon them, and place them together so that their outside edges are parallel. Insert them in that part of the slot which requires to be opened, and, holding a hammer against the head of one key on one side of the link, drive in the other key with a hammer on the other side of the link. After the key is driven as far in as the judgment suggests, measure the width of the slot, so that, if the operation was not performed to a sufficient extent on the first attempt, the operator may judge how much to essay at the second, and so on. To prevent, as far as possible, a slot link or quadrant from altering its shape in the process of hardening, fit into the slot, at various parts along its length, pieces of iron of the same diameter as the die intended to work in the slot, and in quenching the quadrant, immerse it endwise and vertically.

BRASS WORKERS' DANGERS.—Every man who works on brass to any extent must have noticed how his system becomes so permeated by the dust arising from it that all the secretions, salivary and the perspiration, become vitiated by it. This is so grievous that brass workers' shirts in summer time are stained green, and green perspiration exudes from the pores of the skin and stands in beads upon it. The expectoration from the throat is of the same color; and cuts or wounds upon the fingers are very sore, much inflamed, and slow to heal. The average machinist greatly dislikes a prolonged job of brass work. For ourselves, we cannot speak positively of physical discomfort, pains and ailments arising from working on brass, but judging from the lack-lustre eyes, sallow skins, emaciated appearance and general enervation of many brass-workers, we judge that they must suffer much distress. The source of the trouble is from the copper and lead in the brass, principally the copper, for of the latter metal, except in soft yellow brass, there is very little.—*The Mechanical Engineer.*

AMERICAN RAILROAD CARS FOR EUROPE.—As an evidence of the constantly increasing popularity of American made and American style cars abroad, we may state that the Pullman company are now building at their Detroit shops two compartment sleepers and two hotel cars, for the Midland railway of England, and two compartment sleepers for a French road. All these cars will be finished in mahogany, and will be shipped in sections ready to be set up immediately on their arrival at their destination. The hotel cars will have seat arms that drop at the end of the seat as a convenience to passengers in taking seats when the tables are in place. The designs of all the cars are original and in every sense American, and reflect much credit upon the construction department of the Pullman company.

AMERICAN MACHINERY ABROAD.—A gentleman recently from Central America and Mexico, states that there is a general stampede in those countries for American machinery of all kinds, and that European builders are making frantic efforts to retain the trade by depreciating the worth of American-built machines.

The Mechanics of Forty Years.

The contrast between the machine shop of forty years ago and of to-day has some salient points that may interest the present generation of journeymen. There has been no great and sudden change between methods and means of forty years ago and those of to-day, but a gradual improvement that can be readily traced by the workman of to-day who remembers his apprenticeship.

Forty years ago there was no solid iron bed lathe; the best lathes were built on "ways" of southern pine, into which were seated short sections of cast iron to form the seats and ways for heads and carriage. These were seated by means of grooves cut by hand planing, and held in place by wood screws, passing through the casting into the solid yellow pine, almost as hard and enduring as the iron. These ways were shipped and filed to level and then *planed by hand*, an ordinary jack plane being used to smooth the inequalities of the iron and insure an even length. A block of wood grooved to the "ways" was used to finish them by means of emery and oil, and lastly by water and molding sand. Now this looks like boys' play in the light of our admirable systems of planing, finishing, scraping and testing. But some very excellent work was done in the building of tools by these crude methods; and the tools themselves did satisfactory duty for years.

The first planer for iron was similar to that now in use, except for its improvements. Midway of a long table rose the "head," and this held a cross-screw, turned by a wrench and a down-feed screw, also hand-managed. Of course, there was no automatic down-feed or cross-feed. At each end of the frame of heavy yellow pine timbers, reinforced with a rib of iron with a V section, was a roller of timber some ten or twelve inches in diameter, and this was driven by a belt one-half the time of operation, and a similar one at the other end was driven at alternate half times. Each of these wooden rollers engaged with and "took up" a heavy log chain that was connected with the platen.

This was the original planer for iron, and crude although it was, it did excellent work for many years. To be sure, there was a jerk and hesitation about the return, after the chip had been taken, and a sort of deliberation about engaging with the next chip; but when it started it went like a vexed yoke of unused steers, and made things rip.

The lathe was scarcely better as regarded usefulness and exactness. It was a much older tool, but it had never been improved. The cone pulleys of the head *must* be of mahogany or of other close-grained wood, and must also be scored "to hold the belt." The first daring tool builders who cast, of iron, the graded pulleys of a lathe head found all the machinist world against them. It was certain that no belt could hold on a polished iron surface. It was settled that wood was the only proper material for the pulleys of a lathe. At that time—40 years ago—it would have been ridiculed, if it was stated that a continuous screw should be used as feed movement on lathes of more than six feet, and yet all our lathes now are screw feed, no matter what their length. There are establishments which would contract to furnish screws of any reasonable length, from 10 to 50—or more—feet, and engage that the graduation of the thread should not get out of gauge appreciably in that total length.

In an article noticing these improvements, it would be improper to claim that all the present condition and all the past improvement is to be credited to our present race and run of mechanics. We of to-day inherit and use the chances and improvements of those who have gone before. The trials of skill against unmovable matter count for something. We of this later day *do* what our fathers suggested as possible and dared not attempt—or, more likely, had not the encouragement to try.

To-day the workmen—the mechanics of the country—have appliances to do and encouragements to attempt, which were altogether lacking 40 years ago. A machine shop of to-day is a finely finished and furnished dwelling as compared with an uncouth log cabin of half a century ago. The mechanic can use material and appliances which were scarce or costly 40 years ago and his work is as much better than that of 40 years ago as the house is better than the log cabin. But beyond this coarse comparison, it is true to-day as it was 40 years ago, that the real mechanic can do work with insufficient tools, if required, or can create means where the demand is made.—*Boston Journal of Commerce.*

THICKNESS OF LINERS.—To ascertain the proper thickness of a liner or strip necessary to go between a pair of brasses so that (when the faces do not meet) the liner may be placed between them and the brasses, when bolted up tight, without jamming the journal, place a piece of lead wire between the brasses, and then screw the cap down tight, and the lead wire will compress, denoting the necessary thickness of liner. The latter should be made a shade thicker than the distance the wire was compressed, so that the brasses may fit without binding the journal.

QUITE a number of Comstock miners are making arrangements to go out along the line of the Carson & Colorado railroad this spring, as soon as the weather becomes settled, for the purpose of prospecting and working in mines already located.

SCIENTIFIC PROGRESS.

The Origin of Our Moon.

Prof. Robert S. Ball, a somewhat distinguished English scientist delivered a lecture, recently in which he incidentally alluded to the probable formation of our moon in the following terms:

Let us leave the earth for a few minutes, and examine the past history of the moon. We have seen the moon revolves around the earth in an ever-widening orbit, and consequently the moon must in ancient times have been nearer the earth than it is now. No doubt the change is slow. There is not much difference between the orbit of the moon a thousand years ago and the orbit in which the moon is now moving.

But when we rise to millions of years the difference becomes very appreciable. Thirty or forty millions of years ago the moon was much closer to the earth than it is at present; very possibly the moon was then only half its present distance. We must, however, look still earlier, to a certain epoch not less than fifty millions of years ago. At that epoch the moon must have been so close to the earth that the two bodies were almost touching.

Everybody knows that the moon revolves now around the earth in a period of 27 days. The period depends upon the distance between the earth and the moon. The time and the distance are connected together by one of Kepler's celebrated laws, so that, as the distance shortens, so must the time of revolution shorten. In earlier times the month must have been shorter than our present month. Some millions of years ago the moon completed its journey in a week instead of taking 28 days, as at present. Looking back earlier still, we find the month has dwindled down to a day, then to a few hours, until at that wondrous epoch when the moon was almost touching the earth, the moon spun round the earth once every three hours.

We have hitherto been guided by the unerring light of dynamics, but at this momentous epoch dynamics desert us, and we have only probability to guide our faltering steps. One hint, however, dynamics does give. It reminds us that a rotation once in three hours is very close to the quickest rotation which the earth could have without falling to pieces. As the earth was thus predisposed to rupture, it is of extreme interest to observe that a cause tending to precipitate such a rupture was then ready to hand. It seems not unlikely that we are indebted to the sun as the occasion by which the moon was fractured off from the earth and assumed the dignity of an independent body. It must be remembered that the sun produces tides in the earth as well as the moon, but the solar tides are so small compared with the lunar tides, that we have hitherto been enabled to neglect them. There could, however, have been no lunar tides before the moon existed, and consequently in the early ages before the moon was detached the earth was disturbed by the solar tides, and by the solar tides alone.

The primæval earth thus rose and fell under the tidal action of the sun. Probably there were no oceans then on the earth; but tides do not require oceans, or even water, for their operation. The primitive tides were manifest as throbs in the actual body of the earth itself, which was then in a more or less fluid condition.

At the remote epoch of which we are speaking the solar tides were very small, as they are at present. Yet, small as they are, there was a particular circumstance which may have enormously increased their importance. The point to which I refer can be illustrated very simply. We have here a weight of 14 lbs. freely suspended, and here I have a small wooden mallet which barely weighs half an ounce, yet small as this mallet is, I can make the heavy weight swing by merely giving it blows with the mallet. Let me try. I give the weight blow after blow. I hit it as hard as I can, yet the weight hardly swings. I have not yet been successful. The art of succeeding is merely to time the blows properly; this I am now doing, and you see the weight swinga in an arc which is steadily augmenting.

We therefore see that a succession of impulses, in themselves small, can yet produce a great effect when they are properly timed. In the present case the impulses should succeed each other at the same interval as this pendulum requires for one two-and-fro oscillation. The time therefore depends on the body struck, and not at all on the body which gives the impulses.

Just as this pendulum swings with a definite period so the vibrations of the primæval earth had a certain period appropriate to them. Suppose that the liquid primæval globe were pressed in on two quadrants and drawn out on the two others, and that the pressures were then released. The globe would attempt to regain its original form, but this it could not do at once, any more than the pendulum can at once regain its vertical position; the protruded portions would go in, but they would overshoot the mark, and the globe would thus oscillate to and fro. Now it has been shown that the period of such oscillations in our primitive globe is about an hour and a half, or very closely to a half the supposed length of the day at that time. The solar tides, however, also have a period half the length of the day. Here then we have a case precisely analogous to the 14 lb. weight I have just experimented on. We have a succession of small impulses given which are timed to harmonize with the natural vibrations. Just as the small timed impulses raised a large vibration in the weight, so the small solar tides on the earth threw the earth into a large vibration. At first these vibrations were small, but at each succeeding impulse the amplitude was augmented, until at length the cohesion of the molten matter could no longer resist; a separation took place: one portion consolidated to form our present earth; the other portion consolidated to form the moon.

The Wonders of the Spectroscope.

This little instrument combines with its qualities of a trap the advantages of a balance, which we may suppose is fine enough for the most fastidious fairy to weigh the nectar distilled in the dew-drop, or other delicacy of the season.

Our ideas of weight and size are purely relative, and that which seems a small or light object from one point of view may become large and heavy by a different comparison. To most of us, perhaps, a "grain-weight" suggests a little thing; we know that the apothecary and a few other small dealers split up the grain into halves, quarters, tenths and, perhaps, even hundredths, but then we regard them as homeopathic visionaries and laugh at their absurd little pellets; yet, strange to say, there is a vanishing-point in our minds, which, if an object is small enough to pass, it becomes larger and more important by reason of our astonishment and wonder at its minuteness. The most ordinary specimen under the microscope is an evidence of this, but when we realize that the ability of the spectroscope to reveal small particles of matter begins where the finest microscope searches with its highest power in vain, that the grain of matter may be divided, not merely into hundredths, thousandths or tens of thousandths, but into millionths and tens of millionths, and that a single one of these particles may be readily detected by this little searcher and held up for inspection, our wonder and amazement enhance our respect for its occult powers. The astronomer tells us that a comet often throws out a tail longer than the distance between the earth and the sun, and broad in proportion; yet the matter forming this tail is so attenuated that, if properly compressed, a gentleman's portmanteau, possibly his snuff-box, might take it in. Yet we have merely to point this little tell-tale at the comet, and, presto! we know what the matter is. Think of it! Not merely can we grasp infinitesimal particles at our hand, but we may sweep the firmament, gather up the star-dust and tell its composition. But we have not yet reached the end of our excursion; indeed, we have only entered the threshold of the scientist's sanctum, and the wonders of the arcanum eclipse those of the portico. That mysterious agency or force called electricity has been utilized, not merely for the benefit of bulls and bears, or for hundreds of utilitarian purposes with which we are familiarized every day, but it has been used as a fairy finger to probe nature's hidden structure, and, as it were, enable us to *feel* what the spectroscope has revealed to sight.—*Popular Science Monthly.*

The Early Scientists.

The contemplation of the progress of science in our days shows us a whole host of zealous investigators bringing stone after stone to raise to a prouder hight the structure of knowledge whose richly diversified pillars and towers, seemingly disposed without order, all contribute to the common design. From this view we readily turn to the foundations and basement stones of the edifice, which, gray and weathered as they seem to be, yet form the basis of the heaven-aspiring building. Our greatest interest is enlisted in the story of the men who, amid the general perversion of manners and contempt for all learning of the middle ages, lived for knowledge in their study-rooms or shut up in silent cloisters. Although they did not make any great discoveries, they still endeavored to keep alive the little flame which yet shone weakly from the intellectual fires of antiquity. Still more fascinating are such views in the case of men who came out into the life of the times, and, with their sharp minds schooled in the philosophy of the ancients, entered actively into the often erratic course of the world, and by word and writing presented themselves undismayed before those in power—here checking the spirit of boundless avarice and wild excess, there defending the oppressed.—*Popular Science Monthly.*

COLORS AND WARMTH.—It may not be generally known, says London *Truth*, that a man wearing dark clothes is more liable to infection from contagious diseases than he who wears light-colored garments, because particles which emanate from deceased or decaying bodies are much more rapidly absorbed by dark than by light fabrics. This is easy of proof. Expose a light and dark coat to the fumes of tobacco for five minutes, and it will be found that the dark one smells stronger than the other of tobacco smoke.

Bullion Shipments.

We qnote shipments since our last, and shall hs pleased to receive fnrther reports:

Standard, Feb. 20th, $15,513; Northern Belle, 20th, $8,599; Contention, 18th, $20,429; Eureka Con., 16th and 18th, $10,600; Mt. Diablo, 21st, $6,770; Christy, 20th, $2,213; Contention, 23d, $11,085; from Butte M. T., week ending 11th, $46,280; Eureka Con, 21st, $5,368; Star, 20th, $2,497; Leeds, 18th, $960; Germania, 21st, $4,950; Hanauer, 21st, $2,700; Barbee & Walker, 21st, $1,386; Tintic, 21st, $2,001; Horn Silver, 21st, 17 500; Germania, 18th, $5,500; Hananer, 18th, $2,350; Stormont, 18th, $3,750; Hananer, 23d, $9,100; Horn Silver, 20th, $17,000; Tintic Mammoth, 17th, $2,100; Mack Morris, 22d, $10,694.

THE State Congress of Sonora has abolished all tax on mines, mining improvements, machinery and capital invested, and proposes to make a light tax only on the net proceeds of mines.

THE Homestake, the famons gold mine of the Black Hills, has recently struck another enormous ore body.

MINING SHAREHOLDERS' DIRECTORY.

The Mining Share Market.

There is nothing specially worthy of note in the market of this week. At the regular weekly execntive session of the San Francisco Stock and Exchange Board, Wednesday, the committee on the proposed grain call reported progress, and it was stated that when the necessary rules and regnlations governing the new bnsiness had been drafted, a full report wonld he snbmitted for the action of the Board.

The following stocks have been stricken from the San Francisco Board list for non-payment of dues: Buckeye, Dayton, Niagara, Ward, Sonth Justice, Morning Star, Solid Silver, St. Lonis, Golden Gate, Flowery, North Bonanza, Fairfax, Margarita, Concordia (Va.), Monntain View, El Dorado Sonth, General Thomas, Paradise Valley, Real Del Monte, McClintou, Anrora, Sonth Bodie, Sonth Standard, Richer, Crœsus, University, Jupiter, Sonth Bnlwer, Defiance, Mammoth, Glynndale Con., Original Hidden Treasnre, Naumkeag, Caledonia, B. H., Giant and Old Abe, Eagle, East Noonday.

The miuing companies this week paid $405,-750 in dividends.

The Indian Queen Mining and Milling Co. paid its 21st dividend of 2½% at Boston last month. This brings np the total to $318,500. The works are in Esmeralda connty, Nev., and the mine was formerly managed here.

The Vizina Mining Co., of Arizona, paid its regnlar monthly dividend of 10 cents per share or $20,000 Tnesday. Since Nov. 1, 1880, this company has paid five regular dividends of the same amount, and one extra dividend, making $120,-000.

At the Crown Point and Belcher they have shnt down and ceased pumping. The water appears to have been gradnally risiug, notwithstanding that it was snpposed to have ahont found its level last Saturday, as it had yesterday reached the 2300 level. The Yellow Jacket pumps are still kept rnnning, but there is talk that they will he shut down nnless arrangements are made hy which the other companies interested will come forward and pay their proportion of the work. Superintendent Taylor is now in San Francisco and this matter will undonhtedly he arranged, when all hands will join in a determined attack npon the water.

The mnch-desired connection hetween the 2400 level of the Savage and the main incline, says the *Enterprise*, is made at last. A hole was knocked throngh Friday night ahont 10 o'clock. The hlast that did the business was fired from the Chollar-Norcross-Savage side—that is, at the head of the npraise. Had this charge not blown ont a hole, they were all ready to pnt in a charge at the hottom of the incline above. It is really an important connection, and all will rejoice to know that we shall now soon see work progressing in the middle mines. If the connection will do all that is expected of it, it will enable all the middle miues—Hale & Norcross, Chollar and Potosi—to actively explore their gronnd.

NYE, THE LARGEST COUNTY IN THE UNITED STATES.—The Virginia *Chronicle* says: A hulletin just issued from the Censns Office, showing the approximate areas of the several States and Territories, contains mtch matter of curious interest. Texas, the largest State, has an area of 262,290 sqnare miles. Nye county, Nevada, is the largest county in the United States, covering 24,000 sqnare miles; San Bernardino, California, with 23,000 sqnare miles, is the next largest. California has four other counties, each of them as large as Massachnsetts; three that are each larger than Connecticnt; and fifteen others that are each larger than Delaware. Sionx county, Nebraska, contains 21,000 sqnare miles. Oregon also has several large counties—Grant, Umatilla and Lake—contaiuing respectively 17,500, 14,260 and 12,000 sqnare miles. Presidio, with 12,500 miles, is the largest county in Texas. The smallest conuty in the United States is New York, State of New York, and it has the largest population.

A CORRESPONDENT writing from Gray's Harbor, W. T., says: There is quite an excitement on the north side about gold. They are taking ont $20 per ton washing black sand. They have strnck a lead 18 inches thick, running back into the heach. About 20 claims have been taken, and all expect to make fortnnes.

THE citizens of Tnscarora, Nev., have organized a Committee of Safety for the pnrpose of ridding the commuuity of petty larceny thieves and other evildoers who infest it.

SEVERAL good "strikes" are reported in the Total Wreck district, Arizoua. Some of the newly discovered ores are of a high grade and assay quite largely.

IT is said that operations will he resumed in the Tyho mines, and that next snmmer will see the fnrnaces rnnning.

FROST on the Comstock has penetrated mining shafts 700 ft, freezing dripping water at that depth from the snrface.

MINING SUMMARY.

Ths following is mostly condensed from journals published in the interior, in proximity to ths mines mentioned.

CALIFORNIA.

AMADOR.

ZSBLE.—Amador *Ledger*, Feb. 25: We ars glad to say that all reports indicate that this mine is in a prosperous condition. At the new level just opened up, the ore body has widened out to immense proportions—30 ft, it is said. Tbers is snough rock in sight to run ths mill for ysars. A rumor bas gained currency that 40 additional stamps are to he added to tbs mill, but whsther trus or not, we are unable to say. Everything looks as though tbs mine was paying well.

EMPIRE.—This Plymouth mine has been on the improve lately, as regards the quality of ore extracted. It is now tbought that it is on a paying basis. The employees are paid off regularly every month.

PACIFIC.—This mine and mill sre under full headway. No clean-up has been made as yst, but thers is no question that ths quartz will yield handsomely.

SUTTER CREEK.—Some 6 or 8 hands bave been discharged from ths Amador Con. mine. The company have concluded to prospect with less men. Nothing of consequence has been developed as yet, but the company will persevere in prospecting operations, and let us hope that tbeir enterprise will ers long be amply rewarded. The Mahoney is plodding along, keeping ths 40 stamp mill running constantly. The employees were paid off last week. Both sulphuret works are idls and have been for soms time, but they ars expected to start up in ths course of a month.

PLYMOUTH.—Cor. Amador *Dispatch*, Feb. 25: As ws are underground almost all our spare time, ws don't know much about what goes on on top of ground, but in passing to and from our work we notice the two powerful mills—the Empire and Pacific—and hear their thunder as they reduce ths auriferous ore that is entrusted to tbeir ponderous jaws. Ths water supply from the Amador canal pipes is not perfectly establishsd as yet on account of leakags and occasional breaking of the pips, but will be all right in a short time. Those able engineers, Mr Georgs Barbam and Mr. Regan, have it in charge, and will spare no pains to make it carry the water in a satisfactory manner. All the otber quartz mines ars working steadily, sinking or taking out ore. All seem satisfied and prosperous.

BUTTE.

THE TREASURE BOX.—Butte *Record*, Feb. 25: Tbis is the name given to the claim under Table mountain, near Thompson's Flat on ths north side of Feather river, into which tbe company are now running a tunnel. The tunnel is now in 2,200 ft. and has passed several streaks of gravel that prospect well. Tbey are at work on the bedrock, the level of their tunnel running pretty evenly therewith. It may be they will strike the bedrock pitching one of these days, and then it may prove a "treasure box," indeed. It is known that the bedrock is much lower over toward Schirmer ravine than tbo point now reached by the tunnel.

CALAVERAS.

NOTES.—*Mountain Echo*, Feb. 21: A nugget of gold weighing $130 was found by a Chinaman near this place one day last week. The Fletcher Bros. are at present sinking a shaft on Dead Horse hill with favorable prospects. The Monarch M. Co. have bad an offer of $60 per ton for the sulphurets extracted from their gravel mine at Monarchville. John Osborn, one of the owners of the Gold Hill mine, while at work the otber day, picked up a piece of quartz containing over $40. A strike has been made in James Lee's mine in Bald hill, and as high as a dollar to the pan has recently been taken out.

MURPHYS.—The hauling of quartz to the Boston Co.'s mill has been resumed, and we are informed the mill will start up soon. Moss & Stone's mill in Owisburg will start up also on the same Co.'s second grade ore, about the same time. This mill is situated in close proximity to the Red Wing mine. It is said that there is some very fine ore being extracted from the mine, and appearances indicate an abundance of it.

INYO.

KEYNOT.—Inyo *Independent*, Feb 25: Since the resumption of active mining by the Keynot company, under Supt. Fuentes' direction, late reports are quite important. It appears that the San Francisco experts—the doubting Thomases, who have been inspecting the property so frequently of late—had discovered a mare's nest, so to speak; they saw, or pretended to, that the ore breast at the end of the lower tunnel, 130 ft in, was in ore, but that said ore was not rich as that mined out before. Some of the owners were apparently of the same mind, rendering it somewhat difficult for the superintendent to induce them either to go ahead with the work or abandon the plan of selling the mine. The work of opening out the ledge, however, has progressed some 15 ft. further, and the result has been the opening up of an ore chute of body 3 ft wide which averages from $500 to $1,000 per ton! It is a case calling for a renewed examination by these so-called San Francisco "squirts."

MONO.

BODIE.—*Free Press*, Feb. 28: There is nothing to report from the mines to-day which affords any peculiar significance. The Standard Con. sent 1,261 tons of ore to the mills and shipped $29 213 95 to San Francisco. Crosscutting from the 714 level of the Oro was commenced on the 25th. A south lateral drift in the Tioga has been started from the east crosscut, 962 level, and has been driven 13 ft. The bottom of the tbs drift is in quartz of a good quality. The recent activity in Bodie Con. and Mono, which resulted in an advance in those securities, is probably based on rumors of favorable developments on the 800 level of the Lent shaft.

NEVADA.

SPENCEVILLE MINING NOTES.—Nevada *Transcript*, Feb. 25: Mr. Leahy has just returned from the lower part of the county, and says that the mining outlook in the vicinity of Spenceville is encouraging. The copper mining company are working about 90 hands, 50 of which are Chinese. The ores now are reduced by the leaching process. Last month the company paid its first dividend, and the indications are that the stockholders will henceforth realize returns regularly. Mr. Livermore, who lives at Livermore Valley, and 3 others have been prospecting with marked success, their claim adjoining Slater's ranch, a mile and a half below Spenceville. The tunnel is in 130 ft where they have struck a ledge 24 ft thick, and said to be rich. Rock taken by a disinterested person and treated by Supt. Ellis of the copper mine, assayed $1,700 a ton in free gold. The owners feel greatly elated over the strike, which is generally conceded to be one of real value.

PLUMAS.

ONLY RUMOR.—Greenville *Bulletin*, Feb. 22: Several reports have been current on the street for some days about the Plumas National mine. There is not a word of truth in any of these reports, nor will anything be determined on by the company until after Mr. Russel shall return to New York.

MINE OFFICERS.—L. D. Cortright, W. S. Carter, Augustus Storrs, Francis H. Tucker and R. E. Brewster have been elected Trustees of the Gold Stripe Mining Co. The mine is in this district and the election took place in New York. Mr. Cortright was chosen President and Treasurer, and J. J. Pardee, Secretary.

SAN BERNARDINO.

THE MINES NEAR RIVERSIDE.—*Press and Horticulturist*, Feb. 25: On the 23d of February, 1881, several of our citizens became very much interested in the discovery of a fissure of gold-bearing rock, which was traced for two or three miles, starting at a point on the south side of the

Terquesquite arroyo, southeast of town, and extending in a southwesterly direction towards the celebrated Temescal tin mines. Several days and nights were spent in locating claims and many prospect holes were dug. Assays of the rock not proving satisfactory all work was abandoned and the locations were nearly forgotten by the locators as well as the public generally. One day last week another start was made by David Meacham. He brought samples of the rock to town and submitted them to a fire test in a blacksmith's forge. The result was that a metal resembling tin was forced from the rock which spread out upon the shovel as large as a half dollar. This test was repeated several times with the same result. Some of the knowing ones immediately bought up some of the old claims at nominal figures, and in a day's time prospecting was again resumed all along the line. David Meacham entered into a contract with the claim owners to sink a shaft 50 ft and crosscut until the ledge was found, the compensation being a certain interest in the claims. On Wednesday a piece of the rock was taken to San Bernardino, and an assay resulted in finding 2½ per cent of tin. As yet no well-defined ledge has been found, but the croppings are good and the prospects of finding a rich ledge are fair Whether tin or any other valuable metal will yet be found in paying quantities still remains to be seen. We learn that samples of the rock will be sent to San Francisco for further assaye.

SIERRA.

The Ruby Drift Mine.—Sierra *Tribune*, Feb. 23: At the Ruby drift mine a new raise is being run 50 ft above and 400 ft ahead of the main tunnel. Work is being prosecuted in what is supposed to be the main channel, and it is expected to strike pay gravel in a short distance. Whenever this object is gained, the main tunnel will be pushed ahead, and connection made with the drift above. This channel is, beyond a doubt, a continuation of the famous Bald Mountain lead, which has paid dividends to its owners from the time it was discovered, some years ago.

Bald Mountain Extension Mine.—Last Saturday the Extension Co. struck into very fine-looking gravel. The main tunnel had been run east 140 ft, and in raising 22 ft the main channel was tapped. The company had found it necessary to discharge some of their force in the past few days, to await further developments. We are pleased to say that the company's prospects were never better than now for opening out a permanent and paying mine.

Monthly Statements.—The following is the statement rendered by the Sierra Butte Mining Co. for the month of December. Total receipts, $27,393; total working expenses, $20,037. For the Plumas Eureka mine, located in Plumas county, the following was rendered: Total receipts, $43 971, total working expenses, $20,971; outlay on improvements, $591. The Mammoth mill was not run during the month. The Arizona Drift Mining Co. have suspended operations at their mine, and work will not be resumed until the law suit brought by the Carney brothers against them is decided.

Scales Digging.—The Union Hill hydraulic company cleaned up $5 000 last week as a result of 4 weeks' washing. This was very satisfactory to the owners The Fairplay company exploded a powder drift last week which did very good execution. One of the workmen ventured into an adjoining drift immediately after the explosion to see if it had broken through, when he encountered gas. Fortunately he was able to reach the outside but the effect rendered him insensible for a few moments

TRINITY.

Mining Outlook.—Trinity *Journal*, Feb. 25: Up to the present time the prospect for hydraulic mining this season has, on the surface, appeared bad, and, with characteristic despondency, miners themselves have been wont to predict the season a "dead failure" as regards the mining interest. While the facts will not justify us in saying that this will be one of the best years for mining, there are far from upholding the ultra-despondent view of the miners which we have so often heard of late, but the weather, past and present, seems to insure a fully average season. Up to this time upwards of 20 inches of rain and more than 50 inches of snow have fallen at this place, and, while all of this has made little or no water, that very fact augurs well for the water supply in the near future. There has been a long-continued freezing spell, which has checked the flow of water and reservoired it in the mountains, the gulches and the ground at our very doors, and which will now be loosed by the present warm and gentle showers and at once furnish abundant water for mining purposes This supply will in all probability be continuous and last from 3 to 4 months, during which time of constant mining more work will be done than in 6 to 8 months of from 3 to 8 hours water per day, and the profits on such work will be more than in proportion. We expect good hydraulic work from now until far into the month of July, or nearly, if not quite, 4 months' run, and in this event a production of the precious metal in Trinity county fully equal to that of last year.

NEVADA.

WASHOE DISTRICT.

Sierra Nevada.—Gold Hill *News*, Feb. 27: On the 2700 level the north lateral drift has been extended 20 ft. The joint Union Con. east winze has been sunk and timbered 9 ft.

California.—On the 1650 and 1750 levels are still repairing drifts and winzes connecting with the old Con. Virginia.

Ophir —Are repairing the main incline and joint east crosscut on the 1700 level.

Gould & Curry and Best & Belcher Shaft.—The drill from face of the west crosscut was run a distance of 172 ft; total distance from shaft to end of drill-hole, 907 ft.

Con. Virginia.—On the 1650 and 1750 levels are still cleaning out and repairing drifts and winzes connecting with the old Con. Virginia shaft.

Mexican.—On the 2700 level the main north lateral drift has been extended 24 ft. On the 2900 level the main north drift has been advanced 20 ft.

BRISTOL DISTRICT.

Mayflower.—Bristol *Times*, Feb. 18: An important feature has lately been developed in the Mayflower, the ore in the bottom of the winze turning from milling into heavy gray carbonate, averaging 3% in lead, and running all the way from $65 to $2,400 in silver. The uncovering of this rich heavy lead ore in addition to the immense amount of high grade rock in the upper levels, is a big thing for the Bristol company, as upon the erection of smelters, more ore can be reduced per day and worked to a closer per cent. than by the milling process; quicker and larger returns made, and the county benefited generally by the necessary employment of more men and the addition of reduction works to those already in the district.

Strike in the Noonday.—A strike was made last week in the Noonday, adjoining Gilmer & Salisbury's property and quite a whirl of excitement created by the rumor that the "rich float ledge" had at last been found, as at duck the other evening Eugene Howell was seen to have secretly brought down a whole buggy load of specimens closely resembling the float and one piece in particular covered with a green chloride, and which looked as if it would run up in the thousands. It was but a second before the report spread like an electric flash that the "rich float ledge" had been struck. But to ascertain the true facts of the case and upon inquiry of Oene as to where it came from, he knowingly winked and gave us to understand that it was from the Noonday and that he only had 8 lt of it, so we passed. He afterward informed us that a large body of ore had been struck between shaft No. 1 and 2, which, from appearances, would go up in the hundreds. Upon the strength of the strike one quarter of the mine was sold two days ago to a well known party here for $4 a foot. The opealag up of the body of ore in the Noonday has necessitated the resumption of work upon shaft No. 1, which will be put down with all possible speed to a depth of 50 ft below the present cave level and drift run north upon the vein and connection made south with drift from shaft No. 2.

Day.—Drift from 700 level in the Day is in 70 ft, soft open ground with face carrying large bunches of ore and iron. Every indication goes to show that the 620 will be tapped sooner than expected.

Mill.—The Bristol mill is pounding away on high grade rock and turning out more than the usual amount of bullion. A plentiful supply of water on hand and everything running in and about the mill as ordinarily.

Ore.—Ore was encountered last week in the Loro Valo from bottom of winze at end of tunnel No. 1. Since last report the ore is coming in strong though of a low grade, and carrying a heavy per cent. of iron and lead. A few more feet will bring them into the ledge proper where it is thought that the main chimney of ore lies. Everything is favorable to the opening out of a large body of ore at no distant date.

CANDELARIA DISTRICT.

Northern Belle.—*True Fissure*, Feb. 25: Twelve ft have been added to the depth of the main shaft since last report, the total distance made to the 20th inst., being 75 ft. The daily yield of ore has been about 60 tons. Bullion shipments for the week ending Feb. 23d, $15,221.90. Shipments on February account to Feb. 23d, $45,701.78.

Mount Diablo.—The east drift on the second level shows no change, while the ore below the north crosscut, near the center of the mine, on the level, is opening very well and looks promising. It shows a fine body of chloride assaying from $200 to $400 per ton. Bullion shipments for the week have been $8,525.28 on the 18th inst., and $6,770.97 on the 21st inst.

EUREKA DISTRICT.

Better Times Coming.—Eureka *Leader*, Feb. 13: Times in Eureka are bound to improve during the next 30 days, as more men will be put to work and the bullion yield will be increased. In a few days another furnace will be started up at the Eureka Con. on tribute ore. It is said that several hundred tons of this ore is ready for shipment and that a large amount lies broken in the mine. When the new furnace starts up the men who have been so long working and extracting ore with no returns will receive money and spend it, then flush times may be looked for.

Reported Strike.—*Sentinel*, Feb. 25: News was brought to town yesterday afternoon that a strike had been made in the Prospect Mountain tunnel, and some fair looking galena ore was exhibited as coming from the find. Little information on the subject could be obtained. It seems that the miners have finished their contract to open out 100 ft, and the ore encountered is at the point where their job ends and covers the entire face of the tunnel. Mr. R. K. Morrison, the secretary of the company, tells us that the reported strike occurs 1850 ft from the mouth of the tunnel and at a vertical depth from the surface of 900 ft. Some of the stock, which has been held at 50 cents, exchanged hands on the street yesterday at 75 cents per share, the miners who have worked on the contract being the purchasers. It is to be hoped that the find is substantial The policy of the company, so far, has been to push the tunnel deeper into the mountain without stopping to drift or crosscut. Should the present find prove to be extensive they may stop to develop it and take out ore for working.

GRANTSVILLE DISTRICT.

The Centennial Mine.—*Bonanza*, Feb. 25: Work goes bravely on in the Centennial mine with the most flattering results; In the west shaft ore of a very fine grade is encountered. This mine is developing rapidly into one of the finest properties in the district. We understand that it is the intention of the company to erect steam hoisting works, sink a big shaft and open up the mine in good style.

GOLD PARK DISTRCT.

Progressing.—Orontsville *Bonanza*, Feb. 25: Everything moves along steadily in this promising camp. Work at the mines progresses and enough ore is extracted to keep the reserve a good way ahead of the mill. At the mill things are running smoothly and it is expected that the clean-up will make a handsome showing.

IONE DISTRICT.

Sale.—Late advices report the sale of the Ural mill, mines and personal property to an Eastern party, who will incorporate under New York State laws and proceed to business at an early day. The new company will work the Storm King and Victor mines, and will in the spring overhaul their mill and put it in first-class order for business.

Items.—James P. Sargent and Frank Taglaibue, of San Francisco, owners of the North Star and other mines, write they will soon be here to arrange matters for an incorporation on their mines. Mons. Chattel has bonded from Joe Bell an old mine near the Storm King for six months at $4,000. Remarkably rich float found by Mons. Chattel on the ground was the cause of this sudden miae transaction. One thousaud dollars to aid the finding of the ledge this remarkable ore came from is guaranteed.

LEWIS DISTRICT.

Starr-Grove.—Lewis *Herald*, Feb. 22: The main incline on the Starr-Grove mine is being sunk at a good rate. The character of the ore is different from that heretofore taken out, the quartz having a more milky appearance. The ledge is about 6 ft wide. The Bothwell winze is also deepening fast, with a well-defined hanging wall. The width of the ledge is not known as the foot wall has not been encountered. This winze will be a double compartment and is being substantially timbered. The ledge in the stope is in places 9 ft in width, very rich ore running through it. About half the force were laid off Sunday, as sinking only will be prosecuted for the present.

Highland Chief.—Sinking the main incline is still continued; also running the south drift. But little change has taken place in the appearance of the ledge since last week.

Chloride.—The main tunnel on the Chloride mine is still being driven ahead; the ledge is still broken, but the walls are well defined.

Morning Star.—Work on the Morning Star mine is being pushed ahead vigorously. The Morgan incline had attained a depth of 133 ft on Saturday last. The ledge is looking well, and the ore of good quality. A large block of ground is opened up ready for stoping.

Evening Star.—A force of men will be placed on the Evening Star mine right away. The snow has been shoveled off the trail to the mine, and the shaft cleaned out preparatory to resuming work. Samples of ore have been brought down from the mine, some of them looking first rate.

Emma.—The contractors on the Emma mine have made good headway during the week both in sinking and running the main tunnel. The ledge has not been cut yet.

Eagle.—The ledge in the Eagle tunnel has improved greatly during the week, and a large stream of water is flowing from the face. Some good ore is being taken out and the quality improving as the tunnel nears the Sweeney ravine.

Betty O'Neal.—The ledge in the south level of the Betty O'Neal has changed in appearance and is increasing in size. All indications are favorable for striking a large body of ore on this level. The stopes are looking well, and rich ore being extracted. A new feed pump is being placed in position.

ARIZONA.

Prince Rupert Mine.—*Citizen*, Feb. 21: The Prince Rupert mine, in the Wrightson district, owned by Messrs. Hughes & Lyons, is said to be quite a valuable property. The prospecting shaft is down about 80 ft on a vein 16 ft wide, a portion of which will average $300 per ton. Twenty-five tons of choice ore are now on the dump and will, on the completion of the railroad to Casa Blanca canyon, be shipped in Denver for reduction. It is the intention of the owners to sink another shaft about 100 yards westward of the one now down, and stope out the intervening ore. The high grade will be shipped and the inferior piled for reduction later on. The mine is easy of access and near to the line of the new road. Wood is abundant and water sufficient for all necessary purposes. On the whole, the mine is a very valuable one, and will eventually prove to be such to its fortunate owners.

Tombstone.—*Epitaph*, Feb. 26: The Ground Hog is one of the first locations made in the district by Ed. Schieffelin, the discoverer of the mines of Tombstone, and is in no wise inferior to his other locations that have made his name immortal, in connection with this, the best district in the United States. The main shaft is near the center of the claim and is down 35 ft. It shows a vein of rich horn silver ore from top to bottom, that assays from $200 to $2,000 per ton. The ledge has been uncovered for 150 ft south of this shaft and nearly 100 ft north, showing for 250 ft the same rich ore.

Girard.—The music of the stamps at this mine constantly reminds us that we have a new bullion producer in our midst. It is working quite as well as was expected, and will make a handsome record for the mine in the future. The first bullion shipment will be made on the 1st of the coming month

Tombstone M. & M. Co.—The 250 level in Goodenough is now well opened and looks remarkably well, as does also the same level in Tough Nut. The 100 level in Tough Nut is also looking and yielding well. There is no material change in the northwest workings. The Combination mine maintains its former prestige, both in quantity and quality of ore.

Old Guard.—This mine is developing rapidly and richly, and bids fair to be equal to any in that portion of the district. They continue to drift both north and south on the 150 level. The south drift is in 30 ft, with a 2-ft vein of good ore on the hanging wall, with rich bunches all through the ledge.

Contention Con.—Everything around these mines is working along with the usual smoothness, with the daily output of 75 tons of ore.

Vizina.—The drift running northward from the Sumner drift continues to show a large body of ore. The drift on the 400 level is now in 140 ft in length and entirely in porphyry and quartzite. The stopes in all parts are yielding their usual amount of ore, which goes forward to the mill. A dividend of $20,000 has been declared in New York, payable on the 1st proximo, which makes the total dividends to date $120,000.

COLORADO.

Mining Notes.—Denver *Journal of Commerce*, Feb. 18: The Caribou is shipping regularly.....Work has begun on the Big Chief mine.....A rich strike on Fryer Hill has been made within the past few days.....The ore taken out of the Ranchman, Clear creek, has paid for the development.....A lode above old Jimtown, Boulder, has been found that carries heavy lead ore.....The Henrietta mine, on Carbonate hill, struck a rich body of ore during the past week.....The Little Chief, recently located near the forks of the North Boulder creek, shows good ore at a depth of 15 ft.....The boys will be put to work soon on the Bonanza group of mines in Gold Lake central mining district, Boulder.....Cæsar Augustus, located near Balarat, has struck a solid inch of sylvanite running $45,000 per ton gold.....Work is about to be resumed on the Van Buren lode, Boulder. This property has a 10-inch pay streak averaging $180 per ton.....An assay of 24,390 ounces of silver per ton has been had at a 220 level of the Buxtes mine, Clear creek.....The Cosmopolite tunael, situated on Anglo-Saxon mountain Clear creek, is in 500 ft. In 100 ft more a rich lode will be tapped at a depth of 000 ft.

IDAHO.

Big Sale.—Idaho *Messenger*, Feb. 16: The group, known as the Freeman mines, has been sold to the Idaho M. Co., of Salmon river. The consideration was $490,000. This is by far the largest price paid for any piece of mining property in Lemhi county. When the season will permit of mining operations to commence we hope that the property will be put in such a state of development that it will be a permanent and dividend paying property. That Lemhi county has within its boundaries many rich mines has long been known to us, but the lack of means of communication with the outside world and the lack of capital for development have prevented the influx of capital. This period has now happily passed, the time when Idaho mines were at a discount is growing rapidly and beautifully less. The mining resources of our county have been but scarcely discovered, to a limited extent; and we are confident that the year 1882 will witness an era of discovery which the most sanguine of prospectors have not dreamed of.

The Ohio and Ornament Group.—Wood River *Miner*, Feb. 18: Of the many groups of mines tributary to this city, there are none more promising than the group owned and operated by the Ornament G. & S. M. Co. They are located about 8 miles west of Hailey, on Rock creek, and are easily accessible by way of a good wagon road. The most extensive hoisting works on the river were put up on these mines last fall, and 12 men have been steadily at work during the winter. One tunnel is in 180 ft, with an incline down 80 ft on the ledge. A perpendicular shaft is now being sunk, on which the hoisting works are used. The first crosscut from the 60 level in the main shaft exposes 20 ft of ore and ledge matter. A 3-compartment shaft is being sunk which will cut the ledge at 100 ft. The main shaft is now 120 ft, at which depth a level has been started. The ore is milling, and carries ruby, sulphates and native silver. One shipment of 15 tons returned 800 ounces silver to the ton. Fulton Haight, Esq., is superintendent of the Ohio and Ornament properties.

MONTANA.

The Moulton Pumps.—Butte *Miner*, Feb. 15: Yesterday the engine and machinery for the Cornish pumps were set in motion in the Moulton hoisting works. The enormous bob and fly-wheels moved with perfect precision and without sound. The machinery is so tremendous, and the motion so easy, as to amply repay the trouble of a visit to the works. The gearing is what is known as cut gearing, and the engine is now adjusted to an 8-ft stroke. Yesterday, in the Moulton mine, a new chute 3 ft wide, and of first rate ore, was struck on the west 200 level.

The Monoc.—During the past week four carloads of copper-silver ore have been shipped from the Modoc, each containing from 8 to 9 tons of ore. The shaft is now down about 175 ft, 100 ft of contract work having been done on it last summer.

The Belle of Butte and La Plata.—It was learned yesterday from "Uncle" Jack Downs that drifting is progressing steadily in both these mines, and that for the present no more sinking will done in either. There is a large quantity of ore above the present drifts, and as soon as they are far enough in to enable the management to sink a winze for ventilation, stoping will be begun in earnest. In the meanwhile both mines are looking well

Alice.—*Inter-Mountain*, Feb. 15: "Why," said Mr. Hall, "anyone who doubts that we have immense reserves of ore in the upper levels of the Alice has my permission to go down the shaft and examine the mine for himself. I am now going down myself; if you have time I shall be pleased to show you through." The invitation was accepted and Mr. Hall piloted the way through the 100, 200 and 300 levels. On the first are immense reserves of free ore. Some of it is low grade, but assays show it to be of good workable quality. The ledge is wide and the ore clean and compact. On the second level, also, an abundance of ore is in sight, somewhat more base than that of the level above, but yet susceptible of profitable reduction. In both the east and west levels the stopes have been by no means worked out and show thousands of tons of good ore. On the third level, at a point 100 ft east of the crosscut, a big winze has just been started on a body of base ore which measures fully 7 ft across and assays from 60 to 100 ounces per ton. Fifty ft further east is a stope which shows 9 ft of ore, some of it assaying as low as $33, but all of it rich enough to pay a handsome profit. In the face of the west drift, which is now being extended to a connection with the Moulton, good ore is being taken out and the width of the vein is constantly increasing. In the west drift on the north vein the stopes also show extensive bodies of ore.

Bitter Root.—Cor. Butte *Miner*, Feb. 18: The mines of this county (Missoula) are proving to be very rich. Work will be commenced on the Pleasant View, Monday, by Messrs. Bass & Abernethy. Operations were shut down on the 31st of Dec. last, and the mine was then reported played out; the shaft, which is 65 ft deep, soon filled with water so no one could contradict the statement, and on Feb. 6, 1882, Messrs. Bass & Abernethy bought the mine for $500. Upon examination the vein was found to be 4½ ft wide and to carry an ounce of silver to the pound of ore, or $2,200 per ton on an average The Bitter Root Prince is opening up finely. The vein is small, only 2 ft 8 inches wide, but very rich, assaying nearly $5,000 per ton. It is very easily worked, being free milling ore. There are over 200 locations at Sweat House on which nothing is being done, and which can be bought at a very small price. Many of these are fully as good as the claims now developed. The quartz in the Bitter Root country is undoubtedly the richest and most productive with the least work that I ever saw, and I am an experienced miner. We are surrounded by quartz on every side. Sweat House is 7 miles southwest of here. Willow Creek, 10 miles southeast; Woodchuck, 10 miles northeast; Lo Lo, 15 miles northwest, so you see we are in the center of an extensive mining country and are now awaiting further developments. There are over 2,500 locations in those four districts. Woodchuck, as far as developed, is shown to be a mineral mountain, mostly copper and silver. Specimens from the Belle mine show up very finely. Float has been found that carried 50 per cent. peacock copper; also, specimens have been found that carry 1,500 ounces of silver to the ton. Woodchuck is undoubtedly the richest camp here, but the Lo Lo is very nearly as good, only not having so many locations.

NEW MEXICO.

Mogollons.—Socorro *Miner*, Feb. 18: Everything quiet at the Mogollons. Messrs. Parker & Potter are taking out some ore from the mines they sold to Chicago parties, to be sent and tested. Work is being pushed on the Cooney mine, and new discoveries are encouraging. Sluicing on the Miller mine is stopped on account of water. At present there are only 30 men in camp, but they are hopeful and earnest. Snow is a foot deep in the mountains.

Lone Mountain.—A rich strike is reported from Lone Mountain this week. A force of men working on the Penacote mine, owned by W. P. Gibson and S. H. McAnish, last Monday uncovered a body of mineral 3 ft wide; assays run from 152 to 1,140 ounces; native silver can be seen in two well-defined walls 6 ft wide. These parties have secured the extension of the mine south, which is showing up well in sulphurets and gray copper.

The Campe.—*New Southwest*, Feb. 18: Mr. H. M. Meredith, who has just returned from a fortnight's tour among the mining camps, has kindly furnished us with the following items: Eureka district, about 30 miles south of Silver City, is opening out well for the spring work. The Massachusetts Con. Co. is working 50 to 75 men, and probably 200 more are working on their own account in this and Sunny Slope camp. The latter camp is showing up splendidly, with fine prospects of gold and silver. J. W. Knox is down 60 ft, and has struck a 5-ft vein of gold quartz assaying from $50 to $500 to the ton. Apache district lies about 18 miles northeast of Eureka. This is a new camp, and but little developed, but its prospects are bright. Victorio district lies half in Chihuahua, Mexico, and half in Grant county. Developments from 5 to 60 ft show carbonates of silver, with some gold. The outlook is good, but things are kept quiet, as if the property owners thought they had a good thing. Carrisalllo Springs is situated 40 miles east of Eureka. The district is being carefully prospected, but only one mine has been developed, belonging to Obed Foote, Jno. A. Miller and A. C. McComas. Two shafts, about 30 ft each, showed up well in silver.

Coal.—Socorro *Miner*, Feb. 23: Large bodies of coal of an excellent quality have been found near White Oaks, N. M. It is said to be better than the Trinidad coal. In what is known as Camp Edwards, on the Cuchillo Negro range, several new strikes have been made as high as 32 ounces in gold, and large bodies of gray copper have been uncovered. Mr. Will Bowlin, one of the owners of the Virginia copper lode, near South Fork, N. M., informs us that the mine has been bonded to John A. Miller, of Silver City, and W. L. Ryncreon, of Las Cruces, for $40,000.

Copper.—*Lone Star*, Feb. 19: Considerable excitement has been created here and in the Organs during the past week by reports of rich finds in the Jarilla mountains. These are a detached range of mountains situated in the plains, about 30 miles east of the Organs and about the same distance southwest from Dog canyon. The range is only about 12 miles long, and a man can almost walk around it in a day Some 30 miners from Lake valley and the Organs are now there, and others have come in and reported rich strikes. The ores are copper and argentiferous galena. A great drawback to prospecting is the absence of water. Prospectors must haul water from San Augustin. If, however, the mines turn out to be rich this difficulty will be surmounted in some way, no doubt.

OREGON.

Notes—*Sentinel*, Feb. 25: E. K. Anderson, of the '49 diggings, says that he has not done an hour's work in the mine this winter.....The Pacific Co. is pushing work on its ditch out of Wolf creek with 25 hands.....Capt. Kelly is making the dirt fly with his hydraulic pipe in the Coyote creek claim, and expects a rich clean up..... Sturgis & Bodmer are drifting on Jackass creek with a yield of $4 per day to the hand.... Green Bros. are working 8,000 quartz at the Sugar Pine ledge in Josephine county.....Cowaa & Gale are still picking up nuggets in the Birdsey claim, rented by them on Foot's creek .....The Applegate Gravel Co. are busy piping, with plenty of water.....Sterling ditch is cleaned out and ready for water, which is beginning to come.....Blue Gravel and English Co., on Calice creek, are working again with full head. Everything in the Willow Springs camp is in readiness and miners waiting anxiously for water.....T. L. Beck has sold his mining claim and ditches at Willow Springs to Messrs. Ingram & Dean, the consideration being somewhere in the neighborhood of $1,000.

UTAH.

Grand Gulch Mines Bonded.—Silver Reef *Miner*, Feb. 18: Mr. Edward Riley, of New York, has succeeded in bonding a controlling interest in the stock of the Grand Gulch Copper M. Co., at $2 per share, and the same is placed in escrow for 30 days; the balance of the stock is optional with holders at the same figures. This secures little short of giving away one of the most valuable copper properties known. If the sale is consummated, of which there can be no doubt, the new owners will soon demonstrate its true value. Messrs. Adams will be fully reimbursed for expenditures under their present lease, which will be relinquished.

New Incorporations.

The following companies have been incorporated and papers filed in the office of the Superior Court, Department No. 10, San Francisco:

Eureka G. M. Co., Feb. 23. Capital stock, $10,000,000. Directors—Frank Shay, Jerome B. Brown, Fred Morris, Chas. E. Creen and J. E. Foulds.

San Francisco Pavement Co., Feb. 23. Capital stock $500,000. Directors—Frank Shay, Peter B. Quiolan, F. C. Siebe, H. B. Tichenor and T. W. Hinchman.

Winona M. Co., Feb. 25. Location, Antelope Neck, Sierra Co. Principal place of business, Sierraville. Capital stock, $500,000. Directors—E. L. Case, L. B. Keyes, T. S. Battelle, J. S. Ouynn, B Lemmon, J. A. Gleason, F. M. Rowland.

Quartz prospecting has broken out anew in Eastman gulch, a few miles above Lewiston on the Trinity river, and big results are liable to occur any day.

One hundred and fifty persons are reported to have been killed by an explosion in a coal mine at Leoben, Styria.

Comstock Inundation.

Source of the Gold Hill Water Flow.

On the 12th of this month the north drift on the 2800 level of the Exchequer mine encountered a large body of hot water. The water flow, in excess of the water which was then being pumped from the mine, has been variously estimated as being from 100 to 120 miners' inches in volume. Taking the latter figures as more nearly correct, the flow is equal to 1,500 gallons a minute, or 90,000 gallons an hour—no insignificant stream in itself. This water has since shown no abatement, and has so far exceeded the capacity of the pumps in that locality that it has risen in the Jacket shaft to a present point between the 2500 and 2600 levels, and has flown from the Yellow Jacket to the 2560 level of the Belcher, and thence to the 2275 level of the Overman, suspending prospecting operations in the Exchequer, Alpha, Con. Imperial, Yellow Jacket, Belcher, Crown Point and Overman mines. Notwithstanding Jacket's considerable pumping capacity (100 miners' inches per 24 hours), the water has gained steadily, although it is now believed that it will soon be under control. When the body of water was first struck in Exchequer, nine days ago, it was suggested that, inadvertently, the west wall had been cut, either by a diamond drill hole or by the drift. Subsequent inquiries, however, revealed the fact that no drill hole or drift in the Exchequer had been run within 200 ft. of the west wall. It has been further ascertained that a large body of quartz was encountered lying to the east of the regular footwall in an almost vertical position, and probably rising several hundred ft. above the 2800 level. Its existence in the Bullion and adjacent mines has long been suspected, and the fear of water alone has prevented prospecting along its supposed direction. The action of the water in the Yellow Jacket mine indicates that the bottom, or at least the lower portion of this quartz body, has been encountered. Ore bodies on the Comstock have mostly occurred in such outlying branch fissures, and the occurrence of bodies of water has often been revealed in such fissures. Many will remember the flow encountered in sinking the Con. Virginia shaft, which flooded the Latrobe tunnel for months. It is also fresh in the memory of Comstock miners that bodies of water were struck while developing the 1300, 1400 and 1500 levels of the Con. Virginia and California mines. It is a fact beyond dispute that with depth the Comstock ore bodies have increased in size and richness as their occurrence has been less frequent. From the surface to the 1,000 level eleven bodies of ore were encountered, yielding a net profit of $22,000,000; from the 1,000 level to the 2,000 level three bodies of ore were found, yielding about $100,000,000 net profit. With the increased size and richness of ore bodies an increase must also exist in the generative medium. Water being the medium acknowledged to have formed ore, its increased quantity must point to an increased size of ore bodies. It is possible that only one ore body will be found between the 2,000 and 3,000 levels of paying qualities, and it is quite possible that its first appearance has been indicated by encountering such an immense body of water in the north part of the Exchequer mine. The water encountered on the 2800 level will relieve the upper portion of the branch fissure, and that part above, after the water has found its level, will be dry. To demonstrate the existence of ore at this point a drift might be run from the lower levels of the Bullion mine east to intersect this fissure, the lower workings of the Bullion not being flooded and having no connection with any of the mines before mentioned. In the event of ore being encountered, a consolidation of the other mines could easily be effected for the purpose of draining the lower levels of the Jacket through the Bullion's new shaft, by placing in that shaft pumps capable of handling this flow of water.—*Virginia Chronicle.*

Chief Justice Waite's Great Mining Decision.

The United States Supreme Court, Chief Justice Waite delivering the opinion, recently laid down some fundamental principles in mining law, which merit the closest attention of those interested. There appears heretofore to have prevailed in many of our camps some very loose, and, in the light of the present decision, erroneous ideas regarding the legal definition of *possession, relocation* and *consequent rights.* The law is now laid down to be, that *possession* is the *right of possession* acquired under the acts of Congress and local laws and regulations. The possession must be actual until such laws and regulations are complied with, but thereafter and until a legal forfeiture occurs the right of possession is guaranteed to be an actual possession even against a peaceable entry. Any acts done in trespass of such presumed and legal right of possession, though peaceable, are declared to be "as if they never had been done." It is also decided "that a location to be effectual, must be valid at the time it is made," and "what has been once located under the law shall not be relocated until the first location has expired," which, being construed in effect, means that a strict regard must be paid to rights of prior locators, if any, and that jumpers will not be countenanced in asserting a title until they have lawfully acquired one. We quote: "The law fixes no time within a year when the work must be done. Consequently, if done any time during the year it is enough, and there can be no forfeiture until the entire year has gone by. * * * And the work, if completed on that day (Dec. 31), would be just as effectual for the protection of the claim as if it had been done on Jan. 1 previous." In short, the U. S. Supreme Court seems disposed to sit down on the "shot-gun" policy of holding mining claims, in favor of peaceable and lawful methods, deprecating, very properly, any legal construction that would "encourage unseemly contests * * which would be followed by breaches of the peace." A peaceable entry, however, on mineral lands, coupled with the right of possession, is declared to be an ouster of all other claimants. It is important to know, also, that territorial laws of limitation not in accordance with the laws of Congress are ineffectual, except for trespass in local courts, and must yield to the paramount interests of the United States when the question of title is concerned.

The Development of New Mexico.

This portion of the great West, almost unheard of a few years ago, is rapidly coming to the front as a rich and extensive mineral field. Mining excitement runs high, and new districts are being opened all over the Territory. Capital is coming in from the East; large sales are being made; bright, newsy and enterprising journals are published in nearly every mining camp, and the whole region is undergoing what may be termed a genuine mining boom. And what has brought all this about? The answer is given in one word—railroads. Before the advent of the iron horse, New Mexico was scarcely heard of, except in connection with her cattle and wool interests. But when the Atchison, Topeka & Santa Fe line penetrated the region, it threw off the lethargy which so long had bound it, and is, to-day, one of the most progressive Territories of the West.

Notwithstanding that the bullion product of New Mexico is insignificant, compared with Arizona, she has succeeded in interesting heavy capitalists in her mineral fields, and attracting the attention of mining men in the great centers of the East, and solely because she has rail facilities for comfortable travel and cheap and rapid transportation. We feel certain that northern Arizona has mineral beds equally extensive as our sister Territory. Without drawing any invidious comparisons, we can assert, as the opinion of miners and mineralogists, that the mineral belt of northern Arizona is second to no portion of the West. Its richness has been proven by the production of bullion under circumstances the most adverse. And, yet, while one dollar is being invested in this part of Arizona, one hundred are being invested in the mines of New Mexico. To a mining country railroads are a vital necessity. They are the arteries through which course the active life blood of its prosperity and advancement. Without them industrial death is its normal condition.

Arizona cannot have too many of them, and we hope to see the day when a network of iron bands shall cross our Territory from the line of Utah to the Sonora border.—*Arizona Democrat.*

BRISTOL.—The Bristol *News* says of the prospects of its camp: The prospects of Bristol becoming a good camp are certainly bright. We have many mines that can show magnificent bodies of ore uncovered, ready to be taken out and shipped to the reduction works. The Mayflower has enormous quantities of the precious metal running high in the hundreds. The Day has already two grand bodies of rich rock in sight, the extent of which has not yet been ascertained. The Tempest has a large quantity of good rock ready for shipment, as has the Iron mine. The Noonday is looking well, and promises to become one of the leading mines, while the Volcano can show a large and rich ledge. Besides these leading mines, there are several brilliant prospects, with wide ledges assaying very high. The character of the ore is mostly carbonates of different kinds, going about 60% in lead, and will consequently have to be run through furnaces. These mines are on the same mountain range as Piocbe, and though the rock is different in being smelting instead of milling, as the Meadow Valley and Raymond & Ely ores are, there is no reason why Bristol should not loom up to be as wonderful a camp as was Piocbe in its palmy days.

A CREATURE OF ENDURING WEALTH.—The great results achieved through the mining industry are daily becoming more apparent. It not only builds and peoples the waste and desert places, and adds a real, indestructible stream of wealth to the treasury of the nation, but also quickens and vitalizes the forces and powers, and strengthens the foundation of every other business enterprise of the country. Capital is the nation's right arm of power, and the bulwark of strength and security in the time of war or peace, and mining furnishes this most directly and rapidly. This producing force is strengthened by its own growth and development. Let a double yield be gathered from the grain fields of the country, and prices fall; but let our mines throw a double portion of their products into the arteries of trade and values increase in every department of business activity. Mining, true and legitimate, is the creation of enduring wealth, and its success, when developed as business, will touch and quicken with its vitalizing force the sluggish pulse of every human activity to the remotest bounds of civilization.—*Silver Reef Miner.*

Patent Business.

Patents Are Virtually Contracts

Between inventors and the public. The consideration flowing from both parties to the contract is expressly fixed by statute. The Government requires the following consideration in every case: First, that an applicant for a patent shall disclose a new and useful improvement, of which he is the first and original inventor. Second, that the invention has not been patented, or published in a printed publication, prior to the date of his *invention.* Third, that the invention has not been in public use, or on sale, more than two years prior to his application for a patent. Fourth, that the invention shall be properly described and claimed in the specification forming a part of the patent. Provided an inventor complies strictly with these conditions, the Government guarantees that the inventor shall have the exclusive right to make, use and sell the thing invented for the term of 17 years.

The Patent Law provides that in case a patent, which is the evidence of the contract, is not executed in compliance with the requirements of the law, it may be annulled and rendered void. Hence, it is of the greatest importance to every inventor that his patent or contract be skillfully and accurately drafted, that it may afford him complete protection for his invention during the life of his patent.

Secure a Good Patent.

An inventor should first ascertain whether or not his improvement has been patented to another. This requires an exhaustive search among all the patents in the class to which the invention relates. This question can often be answered gratuitously by us immediately on receiving full information of the invention, by reason of our long and extensive practice as patent solicitors and editors and publishers of first-class scientific and industrial journals during the past 20 years and over. When the question of priority of invention is not so readily to be determined, it is generally best to make what is termed a "preliminary examination," by searching through the patent office reports among the patents in the class to which the invention relates, and referring to our extensive patent library, containing compilations of special classes of American and foreign inventions, mechanical dictionaries, scientific encyclopedias, files of scientific and mechanical newspapers, and an immense number of patent applications by inventors of the Pacific coast, carefully filed by this office since 1860.

If, by this "preliminary examination," the improvement is found to have been previously invented, our client will receive for the small fee of $5 for the examination a verbal or written report showing definitely whereby his invention has been anticipated, thereby saving him further expense, and perhaps much time, useless delay, anxiety, etc. When the invention is found to be patentable, the fee for preliminary examination is applied toward the payment of the remaining fees, so that a preliminary examination by us really costs the inventor nothing extra if an application for a patent is finally made.

To avoid all unnecessary delay, however, in securing patents at the earliest moment practicable, inventors will do well to forward a model, drawing, or sketch, with a plain, full and comprehensive description of their invention (stating distinctly what the particular points of improvement are), with $15 as a first installment of fees. A preliminary examination will then be immediately made, and if the invention is found in an earlier patent, we will return $10 to the inventor, and retain $5 for services. If, on the other hand, the improvement is deemed to be novel and patentable, the necessary papers for an application for a patent will be prepared immediately, and forwarded to the inventor for his signature. When the inventor receives the application and finds it duly prepared, he will carefully sign and return the same plainly addressed to us, with postal money order or express receipt for the balance ($25 or upwards) of our own and the first fee of the Government. The case will then be promptly filed by us in the Patent Office, and vigorously prosecuted to secure the best patent possible. [This course is the most expeditious and satisfactory, as no time is lost in transmitting correspondence relative to the preliminary steps to be taken.] When the patent is allowed, the inventor will be duly notified, and on sending the final Government fee of $20 to us, we will order the issue of the patent, and forward the same as soon as it is secured from the Patent Office.

When the invention consists of a new article of manufacture, or a new composition, samples of the separate ingredients sufficient to make the experiment, and also of the manufactured article itself must be furnished.

Models and Drawings.

Models are now seldom required by the Commissioner of Patents, and generally only in intricate cases. Perfect drawings of practical working machines are considered more satisfactory to the Patent Office than the old and more cumbersome system of storing up an immense bulk of almost numberless models.

Drawings or sketches sufficient to illustrate clearly the invention, with a sufficient description to enable us to make a full set of perfect drawings for the Patent Office is all that we require. A model will answer our purpose as well, however, in cases where the inventor can more easily furnish it for our use.

The value and even the validity of a patent often depends on the character, clearness and sufficiency of its drawings. There are thousands of existing patents in which the improvements are but partially or very poorly illustrated in the drawings. When an attempt is made to dispose of such patents, the vagueness and defects of the drawings often prejudice capitalists and manufacturers against the invention, while in reality it may be of great value, and would meet with ready sales had the invention been fully portrayed by artistic and skillfully executed drawings. Again, when patents of this character are brought into court, the uncertainty and ambiguity of the drawings enable the opposing experts to mystify the judges as to the construction or combination of parts intended to be covered by the patentee. In all cases prepared by us, the drawings are made under our personal supervision, by skilled draftsmen in our constant employ, and every precaution is taken that the invention is fully and clearly shown by different views, so that the improvement will be readily understood by the Examiners in the Patent Office, and comprehended by the public when the patent is granted.

In the Patent Office

The application is assigned to the Examiner having charge of the class to which the invention relates. The case must then take its turn with others in the order of filing, and in due time is carefully examined to test the novelty of the invention. If the Examiner fails to find anything that anticipates the invention, a patent is immediately allowed, provided the specification and claims are drafted in proper form. Should the Examiner find a prior patent which, in his opinion, anticipates one or more of the claims the application, a letter of rejection is sent to the attorney in charge of the case; and if the attorney coincides with the views of the Examiner, the claims rejected are erased. In preparing applications for patents, an attorney should be careful to familiarize himself with the class of inventions to which the application pertains, so that the specification and claims may be drafted as nearly perfect in the first instance as is possible. This course saves much time in prosecuting the application to a patent.

When claims are improperly rejected on patents which do not anticipate the spirit or wording of the claims, proper steps are immediately taken to convince the Examiner of his error. This is done, in most part, by personal arguments, as the differences in construction, operation, function and results are more readily discovered and appreciated by an oral presentation of the facts than can possibly be done by relying solely on written arguments. In order that the Patent Office record of the patent shall be complete, an oral argument is generally supplemented by a manuscript brief, that others, in examining the files at any future time, may clearly comprehend the position taken by the Examiner and attorney in prosecuting the case to patent.

In addition to our own personal attention to the interests of our clients here, we have, for over 12 years past, had constantly in association with us in Washington, one of the soundest legal counselors and ablest of practitioners in patent business in this country, who carefully attends in person to our business at the Patent Office and has attained success in a most marked degree.

Perfect Claims.

The value and force of a patent are dependent on its claims. A patent may disclose to the public the most important and valuable invention, and yet the claim be of such meager scope that the patent is actually worthless. When the claims of a patent are so loosely drafted that infringers can flood the market with improvements, differing from the improvement disclosed by the patent only in slight changes in construction and arrangements of parts, such a patent is valueless to the owner, as it fails to afford him that exclusive and complete protection guaranteed by the Patent Law. Hence it is that the greatest care, skill and perseverance are required, first in properly drafting the claims in the first instance, and, second, in prosecuting the application before the Patent Office, and maintaining the rights of the inventor to claims as broad and sweeping as the invention will warrant. This latter is no easy task. The Examiners of the Patent Office serve in the capacity of attorneys guarding the interests of the public. It is their sworn duty to exercise the greatest care and watchfulness, that patentees do not secure claims of greater scope than they are justly entitled to. It is but natural that Examiners are sometimes in error as to just what scope should be accredited an invention. Although the Examiners act under honest convictions in cases where they refuse an inventor his just rights, yet it is the duty of the attorney to maintain the claims of his client, if he is convinced that they are just and proper. To succeed in this requires the display of tact, firmness and ability; and when the Examiner is made to see that the inventor is honestly and fairly entitled to the claims which have been rejected, he will almost invariably recede from his former action, and allow the case.

Advantages to Inventors on the Pacific Coast.

The firm of DEWEY & Co., (continuously editors and publishers of the MINING AND SCIENTIFIC PRESS, nearly from its early commencement in 1860), offer comparatively far better facilities to the local inventors of the Pacific States and Territories, than are possessed by any other agents in America. Members of the firm give personal attention to the applications entrusted to their care. They have been longer in practice in patent soliciting than most agents who are still personally engaged in the business. They have secured more U. S. and foreign patents in the past 20 years (with very few exceptions) than any other firm still existing. Their practice has been so successful and long continued that the great majority of inventions on this side of the American continent have been patented through their agency, thus affording them great and valuable experience, by thorough information of the true principles and points of novelty in the inventions, whether general in character or peculiarly local to this coast.

The extensive business combination and experience of this firm is undoubtedly one of the most fortunate in existence for affording inventors prompt and reliable advice and the best possible facilities for securing their full patent rights with safety and dispatch at uniformly reasonable rates.

Every patentee of a worthy invention is guaranteed the gratuitous publication of a clearly-stated and correct description of his invention in one or more of our influential and reliable newspapers, affording just the circulation that is best calculated to widely inform the class of readers most specially interested in the subject of his invention.

Saving of Time, Etc.

Inventors on this coast will find that owing to our familiarity with inventions and local affairs of this coast, we can more readily and fully comprehend their wants, and thus save much of the time ordinarily consumed in preliminary writing back and forth when distant agencies are employed.

Caveats.

A Caveat is a confidential communication made to the Patent Office, and is therefore filed within its secret archives. The privilege secured under a caveat is, that it entitles the caveator to receive notice, for a period of one year, of any application for a patent subsequently filed, and which is adjudged to be novel, and is likely to interfere with the invention described in the caveat, and the caveator is then required to complete his application for a patent within three months from the date of said notice. Caveat papers should be very carefully prepared. Our fee for the service varies from $10 to $20. The Government fee is $10 additional.

To enable us to prepare caveat papers, we only require a sketch and description of the invention

Rejected Applications.

Inventors who have rejected cases (prepared either by themselves, or for them by other agents), who desire to ascertain their prospects of success by further efforts, are invited to avail themselves of our unrivaled facilities for securing favorable results. We have been successful in securing Letters Patent in many previously abandoned cases. Our terms are always reasonable.

Inventors who do business with us will be notified of the state of their application in the Patent Office, when it is possible for us to do so.

DEWEY & CO.,

The Engineer.

Electricity as a Motive Power.

The development of electricity as a motive power is an aim which, though difficult of realization is yet strongly to be desired. Its achievement is not, however, so very far off, if we may take the utterances of some of the best authorities on the subject as conclusive evidence of the probabilities of the future. For example, M. Bontoux, presiding last week at a meeting of the Parisian Society for the Utilization of Electric Force, observed that the artisan who needs a little motive power for his work, is forced to seek it in the employer's factory, while the thousands of workmen and workwomen wear out their bodies and destroy their strength in impelling the sewing machine, the lathe, and the other motive powers of small industry. The division of electric energy is destined to effect an entire revolution in this sphere. The day will come, and sooner than is imagined, when the artisan family will soe enter their dwelling by means of a magic wire the force which is now so costly to them, and this will be the democratization of force in the benefit of the working class. The solution of the question of motive force for mechanical industries is by this apparently not far distant, and it is curious to contemplate the changes in our social and public arrangements which such a development of the electric motor would accomplish. If an efficient, actuating agent for small machines of every kind could be readily obtained and cheaply purchased, what a revolution would come over the existing labor market. How many workshops for men and work-rooms for women would be closed, the quondam employes being supplied in their homes with the means of carrying on their work in their own apartments. Without attempting to foreshadow all that might happen, certain it is that the cost of driving lathes and machines of every kind would be largely diminished, and the means and motive for extending their application supplied. From all points of view it is much to be wished that this novel mode of actuating machinery may be developed so that its efficiency and economy may establish a reputation, and be largely patronized by both large and small employers of labor.—*Building and Engineering Times.*

Underground Telegraph Wires. — The present much mooted subject of underground telegraph wires is by no means a new one; neither are the practical difficulties attending such a system new. The first telegraph line ever constructed—that from Baltimore to Washington—was first laid underground, but it could not be made to work until it was placed upon poles as at present. Telegraph builders have ever since been trying to devise some means by which the current can be made to work as well underground as above. As yet, however, the problem is not considered fully solved, although in some parts of Europe sufficient progress has been made to introduce underground telegraphy to quite a considerable extent. Extensive experiments in this direction are also now being made in the United States.

Ancient Schemes for Isthmus Canals.—A Spaniard named Zaragoza has been writing for the Geographical Society of Madrid a series of articles on ancient schemes for building canals across Central America, connecting the Atlantic with the Pacific. It appears that so early as the 16th century, the Spaniards had selected three places in that country for canals. They were by way of the Isthmus of Tehauntepec, in New Spain, now Mexico, the river San Juan, or the lake of Nicaragua, the Chagres river, and other parts of Panama. The first scheme, he says, was abandoned, to be mooted again in the present century; those of Nicaragua were actively pursued in the 17th century, and were on the point of being executed.

The Weight of the Brooklyn Bridge.—In a recent report in regard to the weight and carrying power of the East River bridge, Engineer Roebling said that the aggregate strength of the cables is 12,300 tons, and the elastic limit is 8,200 tons. The floor beams in the superstructure will sustain 140 tons each. The total weight of the bridge, with its transmitting load, is 17,780 tons; weight of main span, loaded, 8,120 tons, of which the cables and the long stays support 6,920 tons, and the trusses and short stays, 1,180 tons. The reason assigned for increasing the hight of the trueses was, that the bridge should be used for every purpose to which it would lend itself.

The *Engineer* states, on the authority of a German journal, that there is a scientific reason why green or brown bottles are preferable to bottles of colorless glass for holding liquors. A disagreeable taste is acquired by liquors put into white bottles, which the same liquors are wholly free from when kept in bottles colored green or brown. Blue and violet bottles are stated to be as objectionable as white ones in the respect mentioned.

Bill Williams' Fork.—The copper properties along the fork are beginning to attract the attention of capitalists. There is a lively demand for copper, and experts are constantly in the field searching for that mineral in the interest of would-be investors.—*Yuma Free Press.*

Useful Information.

A New Use for Cotton.

That there is a new era dawning upon the South, so far as manufacture is concerned, will be conceded by every practical business man of intelligence. All over the Southern States there are numerous streams with ample power for manufacturing purposes. These streams never freeze, nor do they dry up, droughts being less frequent here than in the north. Labor is cheaper in the South, because living is cheaper. Houses cost less, food less and fuel much less, from the fact that not much more than one-half is used. In addition to these advantages, and hundreds of others that might be mentioned, it is not amiss to say that in Georgia cotton and woolen mills are, by an act of the Legislature, exempt from taxation for 10 years from the time of their erection. There is not a single use to which we can put the fleecy staple on our shores but what saves transportation and adds so much wealth to the country.

These thoughts are suggested by a New Orleans exchange, which states that Mr. Thos. H. Dunham, a rope maker of Boston of 40 years' experience, states that over 150 tons of hemp rope is made in the United States daily, and that the hemp is mostly imported. He also says that the cotton fiber is preferable, and that cotton rope can be made for 50% less than hemp rope, and that cotton rope is better for all shipping uses, cables, bolt rope, halliards, tow ropes, hawsers, tackle and falls, hoisting, etc. For caulking, he holds that it is superior to hemp, and believes that it can be used for roofing, and instead of duck, and as a substitute for leather and rubber in hose and belting, and for tubing to enclose telegraph wire and telephone wire, both overhead and underground. In fact, if all that Mr. Dunham claims for cotton is hereafter justified by practical use, the great staple will possess a value incalculable.

That this new use for cotton can be made a profitable manufacture there is little question. Congress has authorized the Secretary of the Navy to introduce cotton cordage into the naval service of the United States, to such an extent as will furnish a fair test of its value and efficiency as compared with the kinds now in use. The bill, which originated in the Senate, was reported from the house committee on naval affairs by Judge Elam, of Louisiana. There are many considerations in favor of the experiment. The North has supplied the navy with cordage for over 50 years, and the introduction of cotton will give the South a chance to share in the manufacture. Besides, the production of the fiber at home will make the country more independent of foreign sources of supply. Tar, one of the materials used, is also a Southern production. Russia and Manilla hemp should not be imported into this country. We can raise hemp ourselves, and we can substitute other fibers and be less dependent. This is the true principle of national greatness, of Southern prosperity, and of individual plantation success —never buy what you can produce.—*The Tradesman.*

Pine Oil.—A. M. Stanley, of Wilmington, N. C., has discovered that there is literally such a thing as "fat pine," and has invented a machine with which to make pine oil from slabs and other piney refuse from mills. He claims that one cord of light wood will yield 80 gallons of pine oil, worth, at manufacturers' prices, 25 cents per gallon; also, that this cord of wood will net $20. He not only gets the oil, but also 50 bushels of charcoal, which he readily sells at 10 cents per bushel; also, 100 gallons of pyroligneous acid, and 50 lbs. of vegetable asphaltum, making a fine black varnish. The pine oil, which is the principal yield, contains a large percentage of creosote, and has been found to be one of the best preservatives of wood known, protecting it from the attacks of insects and worms, particularly from the teredo, or salt-water worm, which destroys all the piling underneath wharves along the sea coast. If Mr. Stanley's undertaking is a success, he has a fortune at hand. The yearly waste in our pine forests is immense, and if it could be utilized as this invention would indicate, mill refuse could be turned into great profit.

Visual Phenomena.—It is well known that a black object on a white ground will appear to be much larger than it really is. A white stripe, for instance, on a black surface seems broader than a black stripe on a white surface, although both be of the same width. This phenomenon of simultaneous contrast is physiologically explained by Peter Scherffer in this way: When one of our senses receives a double sensation, one of which is active and strong while the other is weak, it will be found that the latter is not felt. This must be particularly the case when both impressions are of the same kind, or when a strong effect from an object on one of the senses is followed by another of the same kind which is milder and weaker.

A Good Dessert for a Change.—Make nice short dough like pie-crust, roll quite thin, sprinkle on some thinly-sliced cooking apples, roll up not too tight, wrap in a thin clean cloth, tie rather loosely, and steam for nearly an hour and a half. Serve with wine sauce or cream and sugar, as you like best. Mix a pinch of soda in the flour thoroughly before the shortening.

Dyeing Leather Gloves.

A new and easy method for dyeing ordinary leather gloves violet, black or yellow is given by the *Moniteur Industriel.* The gloves are first cleaned from all greasy matter by a warm but weak solution of sal soda; they are left in this alkaline bath for about 45 minutes, are then taken out, washed, rinsed and pressed out. The gloves, thus cleansed, are put in their original shape again and *well stretched*, after which they are ready to be dyed.

Dyeing violet. Either aniline violet, or archil can be used, according to the desired shade.

1. The color is applied by means of a brush or a piece of cloth, which is saturated with the coloring matter.

2. The gloves receive, after the first treatment with the coloring matter, several coats of an alum solution, after which they are dried, and after this one or two coats of coloring matter. The coloring solution should be applied warm.

3. Before the gloves are perfectly dry, they are polished with cloth cushions, wrapped up in fine linen, which is the best way to produce the grain.

Dyeing black. The same means are used as above, and all the manipulations can be used. (The coloring matter is the same that is commonly taken for blacks).

Dyeing yellow. This requires less complicated manipulations. A decoction of Persian berries is used with the addition of some alum. Several coats are required, after which the gloves are polished in the same manner as above described.

Asbestos Paint and Fabric.—Some interesting tests have lately been made in England of the value of asbestos paint applied to wood, canvas and other combustible materials. Among other experiments, a piece of light pine wood, about six inches long by four inches square, painted with five coats, was placed for upwards of half an hour in an ordinary grate fire, but, although the wood within was reduced to charcoal, there was no blaze whatever emitted during the charring. A small model theater, built of wood, with net scenes and accessories, was sprinkled with turpentine and set on fire. Every portion ignited and the whole was consumed. A similar model, with the net scenes and the wood framing all painted with asbestos, was drenched with turpentine and set fire to, but the thin scenes were only partially charred at the lower ends with the turpentine flames, while the timbering was not even ignited. Similar illustrations were made with two models of larger size, about four ft. cube, built on a bed-plate of one-inch deal board, and set fire to by a bundle of shavings. The one was burned and the bed-plate set on fire. In the other case, where the framing scenes and the bed-plate had been painted with asbestos, no ignition was effected, and, although the lower portions of the light scenes were destroyed by the fierce flames of the shavings, the rest remained intact.

Good Health.

Drinking Water as a Source of Disease.

I cannot go further into the consideration of these circumstances; I only cite them as evidence of the influence of moisture in the soil so far as it is measurable by the proportion of ground water present. We are more nearly concerned with the relation of the soil to the water which we apply to our own use, which we draw from wells and springs, to water as a vehicle conveying matters out from the soil. When typhus or cholera rages epidemically in any place, two parties immediately set up a contention as to whether the epidemic influence proceeds from the water or the air. It must be admitted henceforth that either is possible, that a so-called sickly soil can impart its noxious properties equally to the water and to the air it contains, but it may also be that only one of these ways is possible as to certain matters and lower organisms. Observation and experiment must decide upon that. Most physicians have hitherto considered that infection was probably most directly conveyed through the water, and the so-called drinking-water theory has been developed from this view. It has, however, been ascertained that the best known infectious agent in the soil, the *Bacillus malariæ*, which Klebs and Tommasi-Crudelli have discovered and studied in the Roman fever districts, cannot live without air. These investigators found that the malarial poison was not communicated to the water that stood over a richly malarious mud. Tommasi says, in his latest work on the Roman malaria and the ancient drainage of the Roman hills, that "the *Bacillus malariæ* is preeminently an air-living organism." Among the conditions favorable to its propagation in a malarial soil—which need not be a swamp soil—Tommasi specifies a temperature of about 20° C. (68° Fahr.), a moderate degree of steady moisture, and the direct action of the oxygen of the air on all parts of the mass. He says further: "The lack of one of these conditions is enough to cause a suspension of the development of the spores and of the increase of the malarial ferment." If anyone, however, believes that this organism must also remain inoperative when it passes into our blood because that is a fluid, he should be reminded that it makes a great difference whether we put such organisms, taken from their airy nests in a moist soil, into cold water, or into warm blood where air is supplied to them from the corpuscles.

We cannot, indeed, answer, with the results of experiment and microscopical investigation, questions respecting the infectious diseases with the specific germs of which we are not acquainted, but we may be guided in the matter by other facts. Naegelli says: "Contagion fungi can keep up their peculiar activity in water only for a short time. The purer it is, the less food they find in it; they are very soon removed by exhaustion in clear spring water; and, even in water that contains food for them and where they can multiply fast, degeneration quickly sets in, and they are changed into common ferments."—"*Sanitary Relations of the Soil,*" *in Popular Science Monthly.*

Simple Remedy for Catarrh and Bronchitis.

It is now generally known that carbolic acid is strongly disinfectant, and very usefully applied to putrid sores or purulent wounds. Wood *creosote* is similar, is decidedly antiseptic, and quite volatile. It is, therefore, natural to suppose it would be useful when applied to catarrhal and bronchial affections which arise from diseased or putrifying mucus. We learned of its use for this purpose from Dr. Peecetto, a leading physician in the noted Italian medical school in Genoa, Italy, from whose conversation we gleaned portions of the important article on "Catching Cold and the Remedies," given in last December's *American Agriculturist.* We have since recommended the following treatment in many cases with the best results. It can do no harm, is simple and is eminently worthy of trial, both for temporary and chronic affections:

For bronchitis: Get from the druggist's a little good wood creosote. Put two drops of it into a bottle holding a pint or so. Pour in a little more than half a pint of clear water, and shake it well; also, shake well always before using it. Take a mouthful of this, throw the head back, gargle it some time in the throat, and then swallow it. Repeat this every two hours, more or less, so as to use up the liquid within 24 hours. For each subsequent 24 hours use three drops of the creosote in three to four gills of water. This three drops a day may be continued as long as any bronchitis appears. Two or four days is usually enough, though it may be continued indefinitely without harm.

For catarrh: Prepare the creosote water as above, to any amount, at the rate of one drop of creosote to one gill of water (four drops to the pint), or a little more water if the creosote be very strong and the water too irritating. Make a fresh mixture once in two or three days and as much oftener as more is needed. Take a handful of this water, previously well shaken, and snuff it through the nose into the mouth and eject it. A little going down the throat will do no harm. Do this two or three times and repeat it at bed time, in the morning on rising, and, if need be, occasionally during the day. In fact, keep the nasal passages washed out with the creosote water. Its vapor will even penetrate the bony cavities, and also be drawn into the lungs with useful results. It destroys the purulent mucus, and tends to prevent its further secretion. It is useful for any discharges from the nose or lungs produced by colds or general weakness.

Women's Health.—"I would," says Gail Hamilton, "that women were happier." The wish meets an evident need, but if Gail had gone to the root of the matter she would have said "I would that women were healthier." It has come to be a commonplace truism that health holds, in itself, the secret of all life's success, but its full significance has never yet been adequately appreciated. Women are too apt to regard the measure of health as met if they are not actually ill. Now, true health is a positive, rather than a negative, state. It is physical exhilaration; it is the state when duty becomes delight, when the surplus energy craves exertion. In this state the keen morning air is like wine, and life takes on a rest, a glow, a sparkle. This is the physical state that renders possible mental enthusiasm, spiritual exaltations. "I'm so nervous," sighs a woman whose life is set in the midst of all comforts and perhaps luxuries. But wherefore? What need is there in being "so nervous," when exercise, sleep, proper food are attainable? "A woman of 20 ought to be as much ashamed of being dyspeptic as of being drunk," severely says the scintillating Gail, and it is true, even if severe. If women can once become regenerated with the fact that a state of vigorous, robust health is quite compatible with intellectual power and refinement, and being only negatively well is not necessarily synonymous with a lady, it will do more for women's advancement than all the ballots she could cast between Boston and San Francisco. Probably, however, she requires the discipline of political enfranchisement to educate her up to wider views of life and its possibilities and deep significance.

Walker Lake District.—Owing to the presence of a superabundance of the "beautiful," only a few claims are at present being worked in this district, which is situated on the south-east side of Mt. Grant, Nev. However, some good prospects are found, and as soon as the snow goes off considerable prospecting will be done.

SAN FRANCISCO:

Saturday Morning, March 4, 1882.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—New Air Compressor; Exploder for Firing Blasts; Debris Case; Microscopical Society, 137. The Week; Working Slimes and Tailings; Foundry Notes; New Quartz Crusher; On Minerals, 144. An Ice Locked Ship, 145.

ILLUSTRATIONS.—The Rix New Vertical Air Compressor, 137. The U. S. Exploring Ship "Corwin," in a nip off Cape Romanzoff, 145.

MECHANICAL PROGRESS.—The Circular Saw; Links; Brass Workers' Dangers; American Railroad Cars for Europe; The Mechanics of Forty Years, 139.

SCIENTIFIC PROGRESS.— The Origin of our Moon; The Wonders of the Spectroscope; The Early Scientists, 139.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Assessments, Meetings and Dividends, 140.

MINING SUMMARY from the various counties of California, Nevada, Arizona, Colorado, Idaho, New Mexico, Oregon and Utah, 140-1.

THE ENGINEER.—Electricity as a Motive Power; Underground Telegraph Wires; Ancient Schemes for Isthmus Canals; Weight of the Brooklyn Bridge, 143.

USEFUL INFORMATION.—A New Use for Cotton; Pine Oil; Dyeing Leather Gloves; Asbestus Paint and Fabric, 143.

GOOD HEALTH.—Drinking Water as a Source of Disease; Simple Remedy for Catarrh and Bronchitis; Women's Health, 143.

MISCELLANEOUS.—Water Jacket Smelting Furnaces; Wealth Produced by Hydraulic Mines; White Mountain District; What Developments on Silver Hill Show; The Sandias—Past and Present; Another Montana Boom; Richness of Cochise County, Arizona; Heat in Silver Mines, 138.

Passing Events.

The argument in the great slickens case began this week before Judge Jackson Temple, at Sacramento. We give in another column a brief note of Mr. Cadwalader's argument. It will not be long now before a decision is given in this most important case. Doubtless, however, it will have to come before the Supreme Court of the United States before final adjudication.

The week has been rendered a notable one in public affairs by the formal tribute paid to the memory of President Garfield by the people of the United States, through their representatives in Congress assembled. The eulogy by ex-Senator Blaine was a calm analysis of the life and eminent services of the murdered President, supplemented by a glowing tribute to his memory, which will find echoes in the hearts of fifty millions of people, who delight to honor his name.

The Governor of this State this week issued a proclamation declaring Saturday, the 4th inst., a legal holiday, the occasion being one when the people will hold mass meetings in different cities and towns and express their views in favor of restricting Chinese immigration. It is intended to impress Congress with the unanimity of the people of this coast on the subject.

A COMSTOCK miner writes to the Virginia *Chronicle*, complaining of the exortionate prices asked for fuel in that city. His monthly housekeeping expenses for himself, wife and three children amounted to $90, of which $28.75 was paid for wood and coal.

FOSSIL remains of animals and fish have been found by a hunting party on the ranch of Mrs. Emily Knot, about 10 miles from Redwood City, on a hilltop nearly 1500 ft. above the sea level.

THE snow is quite deep at Jefferson and surrounding mountains.

Working Slimes and Tailings.

The mode of reduction of slimes and tailings has been improved and economized to so great an extent by the tailings mills, as to allow of the treatment of material which a few years ago was considered worthless. The tailings which the tailings mills on the Carson river work, and which were, in time gone by, produced from Comstock ore, were collected in reservoirs at the various mills, and also in larger quantities on the flats at the outlets of Dana, Gold and Six Mile canyons. Not an unimportant factor in the economy of working these tailings is the low price of quicksilver; nor can the discount on silver bullion be lost sight of. A material change in the price of either might cause an entire suspension of the industry. This fact shows how closely everything is figured down and how small a margin one way or the other causes profit or loss.

The expression "tailing" is generally made to include the slimes or battery overflows, which are by far richer than the tailings proper or pan residues. The slimes settle in the portions of the reservoire least subjected to water currents. In an amalgamating pan the slimes form a pasty mass, which has a tendency to hold the quicksilver suspended and carry it off. To obviate this, sand is added, generally one half, and sometimes twice the quantity. It depends upon the amount of calcareous mineral present. The charges thus prepared do not, as a general thing, assay more than $6 per ton. Mr. J. E. Gignoux, superintendent of the Lyon M. & M. Co., gives to the Director of the Mint a description of the method of working these slimes and tailings, as follows:

The treatment is termed base, as from 15 to 20 lbs. of copper sulphate to the ton is usual. This copper is reclaimed in a great measure by the subsequent refining operation. The process is more successful when the amalgam is not finer than 200. The pans are generally wooden and of two and four tons capacity. Charges are made every four hours. Salt, copper and quicksilver are added at the commencement of the operation, when steam is also given. Simple mullers are used, as no grinding is required. The settlers are of a sufficient size to allow the charge to be diluted with water until quicksilver particles will no longer remain suspended. The charge is kept in motion in the settler for four hours, or until the next pan charge is to be drawn; there being a settler for each pan. The quicksilver is obtained from bowls, which are connected by pipes with the settler bottoms, is strained directly and retorted in large retorts of the usual form. These are gradually heated for about 12 hours. The gold, copper and what foreign matter was present in the amalgam form a spongy mass, which is easily separated from the silver, which forms a compact scale next to the iron of the retorts. By a mechanical separation base and white metal are obtained. These are separately treated, although the refining operation undergone is precisely the same in both cases. The bullion is broken into lumps about the size of an egg and thrown into a moderately heated one-hearth reverberatory furnace. Here it remains several hours, when the metal oxidizes to a certain extent and becomes sufficiently brittle to allow of crushing and passing through a fine sieve. It is then divided into charges and submitted to an oxidizing flame in the furnace, constant stirring being required. The roasted mass is then treated in a bath of sulphuric acid. The copper is taken up as a sulphate of oxide of copper, also a small portion of silver. This is precipitated by metallic copper in the form of fine silver, which is filtered and washed, and when melted is about 999 fine. The residue from treatment of the white metal gives bullion about 985 fine, while the base contains the gold. The liquor from the bath, subsequent to the precipitation of silver with copper, is conducted into tubs and allowed to crystallize into commercial bluestone.

To show the cost of extraction, net yield, etc., in working these slimes and tailings on a large scale we give the following statement taken from the County Auditor's books, of Lyon county, where each company is required by law to file a sworn statement for assessment purposes:

NAME OF COMPANY.	Number of Tons Extracted.	Value per Ton.	Gross Yield.	Cost of Extraction.	Net Yield.
Pacific Mill Company	12,150	$12.47	$149,644.15	$83,856.00	$65,788.15
Union Mill Company	7,155	3.89	27,846.81	19,545.49	8,301.32
Lyon M & M Company	35,329	3.58	128,177.00	116,555.55	11,621.45
Woodworth Mill Co...	11,518	5.53	47,154.12	48,515.38	.....
French Mill	1,560	8.09	12,625.12	2,720.00	9,905.12
Atlanta Mill Company	4,580	3.21	18,929.24	16,905.00	2,024 24
Eureka Mill.....		3.23	8,339.73	5,336.85	2,662 88

The foregoing statement covers four quarters.

MR. B. W. CROWELL, our corresponding agent, will soon visit portions of Santa Clara, Santa Cruz, San Benito and Monterey counties on his route southward in the interest of this paper.

THE Late strike made in one of the Southwestern Company's mines at El Dorado Canyon is reported as turning out handsomely and the hopes of the most sanguine are realized.

Foundry Notes.

The Oakland Iron Works.

It seems somewhat strange that a city, the second in size on the Pacific coast, should have been all these years without a foundry, yet such is the fact. A machine-shop or two, with the blacksmith shops, have comprised all the iron-working industries of Oakland. For the simplest castings people have had to send to San Francisco. The nearness of the great foundries of the city has, therefore, kept back the growth of any very flourishing iron industry in Oakland.

Now, however, Oakland is to have an iron foundry of her own. Ives Scovills, of the Oakland Iron Works, has nearly completed a new building, 100 ft. front on Jefferson and 60 ft. on Second street. The building on the old lot will also be moved up and will thus give the new works a frontage of 100 ft. on each street. The buildings are two stories in hight.

The foundry proper is 60 ft. by 31½ in the rear of the building. At the time of our visit this week the floor was being put in. A traveling carriage, moved by rack and pinion, is for the present to be used instead of a crane. The hoisting gear on the crane carriage will be run by chain wheel from the floor.

The cupola is of medium size, and will be lined up 24 inches. They will be able to take off about 7,500 weight to a heat, for a cast which will require that much. They have a core oven six ft. wide and 20 ft. long, arranged so that the surplus heat from the boiler passes through it, this heat being thus utilized for baking the cores. They expect to be ready to take off a heat in about two weeks, if the weather permits their getting in their floor all right.

Mr. Scoville expects to be able to do all kinds of work, mining machinery, stone breakers, etc., included. The facilities for shipping are good, the railroad passing within a block of the works, and there is a side track there which can be used on occasion.

The old shop is at present busy in fitting out the new one, making an engine or two, and doing repair work and small jobs. Mr. Scoville says, that hereafter people will have no excuse to go to San Francisco for iron work. He has labored under great disadvantages, since in doing jobs, he has been himself compelled to go to the city for any castings, however small. With the convenience offered by the cupola, the enlarged premises and the increased facilities, these works will no doubt get some of the transient trade, as well as their regular line.

Heretofore they have been unable to do any mining machinery work at all, because they could make no castings. Now they propose to compete in this direction, and extend their business. The machinery, tools, etc., of the old shop will be transferred to the new one as soon as the buildings, now nearly completed, are ready for occupancy.

New Quartz Crusher.

Charles P. Stanford, of this city, has just patented through the MINING AND SCIENTIFIC PRESS Patent Agency, a peculiarly operating quartz crushing device. A circular flat-bottomed mortar is secured properly to a foundation or mortar block, and provided with screens. Within this crusher is the mortar or pestle. This consists of a heavy metal block, having peripheral dies upon its under surface, bolted or keyed to it. The mortar is large enough to easily contain the pestle and allow it considerable side play.

The frame of the device has cross guides, in which a vertical shaft is journaled and properly supported. This shaft has secured to it a crank arm, through the outer end of which the stem or handle extending upward from the pestle loosely passes.

The shaft being over the center of the mortar, the crank causes the stem, in order to pass through it, to incline somewhat, and so tilt the pestle to one side. The main vertical shaft is rotated by suitable gears and pulleys.

When this shaft is revolved the crank is revolved and carries with it the stem of the pestle. By holding this stem out at a certain distance and making it describe a circle outside of the vertical central line of the mortar, causes the pestle to tilt upon each of its dies successively, thus producing a crushing and grinding force, the whole weight of the pestle being thrown upon each die as it is tilted by the revolution of the crank; and as the faces of the dies are made in a plane tangential to the radial line of the movement of the pestle, a series of flat surfaces of the dies, parallel to the flat bottom of the mortar, intermittently strike the ore percussively. The stem, by passing loosely through the crank is not revolved upon its own axis, and consequently the pestle does not turn in the mortar.

ASSESSOR WALLACE'S bullion tax books show that the value of ores extracted from the various mines of Eureka district since 1873 amount to $30,046,002.32. Mr. Wallace has no data of the previous four years, as this county was then a portion of Lander, and all the records belonged to that county.

THE Mountain View mining company will soon put up a mill at Hot Creek mining district.

On Minerals.

[Notes of a Lecture delivered before the Mechanics' Institute by A. W. JACKSON, Jr., Instructor of Mineralogy, Petrography and Economic Geology, at the University of California.]

Most persons would resent any imputation cast upon their general knowledge of animals and plants, of the forms of the animal and vegetable kingdoms. In one way or another in the course of our education, the subjects of botany and zoology are brought sufficiently to our attention to give us very good general ideas of organic forms. If we do not get this knowledge at school, it is not at all difficult to obtain it from books, with the help of such plants and animals as can easily be gathered in our daily walks. Now, unfortunately, mineralogy is not taught in our schools, and it is impossible to learn very much about minerals from books without the aid of well-arranged mineral collections. Whence it comes about, that while you rarely meet a person unfamiliar with at least the elements of the organic natural sciences, you just as rarely meet one who knows anything about the inorganic natural science.

I have thought, therefore, that it might be interesting to you this evening, to present a short, necessarily brief, account of the whole mineral kingdom, to give you a bird's-eye view, so to speak, of the whole mineral world, to the end that you may obtain, perhaps, a generalized conception of the mineral composition of our valleys and our mountains, our soils and our ores.

When we consider that the two great industries upon which modern civilization depends for its very existence—agriculture and mining—both draw their raw materials directly from the mineral world, and when we consider, furthermore, that the highest measure of success in those industries is attainable only after a thorough comprehension on the one hand of the mineral composition of soils, and on the other of ore deposits, it would seem that the subject would be full of interest for all.

Let me at the very outset define clearly what a mineral is, and draw the distinction between a mineral and a rock. If you take a colorless quartz crystal and hold it between yourself and the light, you can see that it is perfectly clear, that you have but a single homogeneous substance before you. Now take an equally familiar substance, a piece of granite. You see at once that it is "speckled;" that it is a mixture of three separate, distinct, recognizable substances, black scales which you call mica, smoky gray granules which you call quartz, and dull white granules which you call feldspar. It is a mixture, heterogeneous. You have at once then the leading distinction between a mineral and a rock. A *mineral* is any homogeneous body that is a direct production of nature without the intervention of organic processes. A *rock* is a mixture of two or more minerals. The minerals make up the rocks, while the rocks make up the larger features of the earth's crust.

The minerals are the letters of the alphabet with which the book of nature is written, or at least that volume which relates of her solid structure, while the rocks are the words of the language in which nature expresses her meaning in that book.

Chemistry teaches us that the world is composed of elements. Now while some few minerals, such as diamond, sulphur, gold, silver, copper, consist of but a single element, by far the most minerals consist of combinations of two or more elements associated together in very great variety and proportion. A mineral species comprises all mineral substances possessing the same or equivalent chemical compositions, and a certain fixed group of physical properties, such as crystal form, optical properties, etc.

You will find enumerated in works on mineralogy from 600 to 900 distinct mineral species. Each of these minerals is characterized by a particular group of chemical and physical properties, which distinguish it from all other minerals. The mineral is described by describing all of its properties, and it is determined by determining each of its properties.

Now I shall not pretend to describe single minerals to you to-night, for I could not do so intelligibly unless you were familiar with all these mineral properties in the abstract; but I shall try to give you some account of

The Larger Groups of Minerals.

From the time when minerals first attracted the attention of the student of nature, there have been attempts to classify them, to segregate and arrange them into groups of related substances.

With all of the refinements of modern scientific methods, this has not yet been finally accomplished. There is to-day no systematic classification or grouping of minerals that is acknowledged by all to be satisfactory, nor even to be the best. Evidently, however, if we wish to obtain any *general* idea of the mineral kingdom, we must segregate the minerals into groups. The grouping which I have adopted, (Breithaupt's modified by Weisbach) and which I teach to my students, is curiously enough identical in its main features with the system suggested by Avicenna in the 12th century, A. D.

Without attempting a strictly scientific grouping, admitting even a purely technical idea as a controlling feature in the classification, it yet brings most of the closely-related minerals into the same group, and enables us to obtain the

general view of them which I wish to present, I will present at once the entire system, and will then proceed to characterize the different groups more in detail.

Classification of Minerals.

I. Hydrolites (Soluble Salts)

II. Lithites ("Stones").
- 1. Kuphoxides.
- 2. Pyrites (silicates).
  - a. Silicates (Zeolites).
  - b. Phyllites (Hydrated silicates) (Micas).
  - c. Amphibites.
  - d. Amorphites.
- 3. Amorphites.

III. Metallites (Ores).
- 1. Halometallites (metal salts).
- 2. Metal oxides.
- 3. Metallic metallites.
  - a. Pyrites.
  - b. Galenites (Galenite).
  - c. Cinnabarites (Blende).

IV. Combustibles.
- 1. Sulphur.
- 2. Anthracites (coals).
- 3. Asphaltites (Asphaltum).
- 4. Rhatinites (gums).
- 5. Paraffines (waxes).

Under the head of hydrolites, we group together all minerals that are readily soluble in water. The group comprises about 50 minerals, and the ordinary chemist would at once recognize the most of them as compounds with which he is familiar in his laboratory, while not a few are of common every day use, such as table salt, borax, soda, epsom salt, alum, blue and green vitriol and nitre. Chemically, these hydrolites consist of combinations of two or three of the common acids, like sulphuric, carbonic, muriatic and nitric, with soda, potash, ammonia, lime, magnesia and two or three of the heavy metals, such as iron and copper. Physically, they present nothing striking and often cannot be distinguished from the artificially prepared salts of the laboratory.

Now with respect to their geological occurrence. The original

Form of Occurrence

in nature and the permanence of the deposits of the hydrolites are determined strictly by that property by virtue of which they are classed together, viz.: their solubility in water. They are deposited mostly from solution in water, and in greatest quantity from inland seas, forming widely extended beds covering often hundreds of square miles.

Thus have been formed the extensive salt deposits of previous geological ages that are now found inter-bedded with clays in various parts of the world. Wherever these beds by subsequent disturbances are exposed upon the surface of the earth in countries with moist climate, they rapidly wear away, are dissolved and carried with the drainage water back into the sea. In dry countries, however, like Peru and Nevada, salt beds are actually found cropping out on the very surface. Of such character are the famous nitre-beds of Peru which have figured so largely in the present troubles between Peru and Chili. Similar nitre deposits have recently been discovered in Nevada, although their exact extent and nature have not yet become generally known. Another mode of occurrence of hydrolites is as a decomposition product on ore deposits. Many old miners have doubtless noticed the formation of crusts and stalactites of green and blue vitriol, in their drifts and tunnels, and strongly impregnating their mine waters. These result from the oxydation of the sulphurets of their ore to sulphate of iron and copper which are soluble in water, and crystallize out on the first opportunity.

The occurrence of the common iron sulphurets in very many rocks is the cause of the formation of delicate efflorescences of sulphates on the rock surfaces, to be washed away, however, by the first rains that come. Finally, one of these hydrolites (sal ammoniac) has been detected as a volcanic exhalation.

While the occurrence of large bodies of these hydrolites is thus restricted to countries with dry climate, or buried deep within the protecting solid rocks of the earth's crust in other countries, in small quantities they are being constantly formed everywhere. The solid rocks which compose our mountains, and the soils of our valleys, are constantly undergoing decomposition from rain waters containing carbonic and other acids in solution; the soluble portions are leached out and make their appearance in mineral springs or are carried into the surface drainage and ultimately reach the sea. Examine the analyses of well-waters and river-waters everywhere; they will all show more or less of these minerals in solution, and the aggregate amount that reaches the ocean annually is something enormous. You will observe then the cycle of phenomena constantly recurring. The land continually leached by descending atmospheric waters, insoluble parts left behind, the soluble parts taken to the sea, concentrated, deposited, and elevated again into dry land. The salt beds which we work are the leachings of the rocks of preceding geologic ages, and the leachings of to-day will form the salt beds of coming geologic ages.

Lithites.

The extensive class of stony minerals, containing somewhat over 200 species, comprises the minerals with which you are more familiar as ordinary stones.

They differ from the salts in being insoluble in water, and from the metallites in containing none of the heavy metals as essential constituents. They possess the distinctively stony luster which, from its very common occurrence, is called *common* luster, in contradistinction to that of most ores, which is called *metallic* luster. Finally, they are distinguished from the combustibles by their incombustibility.

We can subdivide this class into three well characterized orders: Kuphoxides, Silicates, Non silicates.

Kuphoxides.

This order comprises the compounds of silicon, aluminum and magnesium with oxygen. It is distinguished by the facts that it contains the commonest mineral, viz., quartz, and also some of the most precious, viz., rubies and sapphires varieties respectively of spinel and corundum.

The leading minerals and varieties of the order may be thus tabulated:

Spinel.

Spinel ruby (carmine).
Balas ruby (rose).
Rubicelle (orange).
Almandine (violet).

Corundum.

Sapphire (blue)
Oriental emerald (green).
Oriental ruby (carmine).
Oriental topaz (yellow).
Oriental amethyst (violet).
Emery.

Quartz.

Rock crystal (colorless).
Smoky quartz (smoky gray).
Amethystine quartz.
Common quartz.
Jaspers, etc.

Opal and Chalcedony.

The chemical composition of all of these minerals is exceedingly simple. The spinel rubies consist of magnesia and alumina, while the corundum gems all consist of alumina only.

Their colors are most exquisite, otherwise they never could take rank as gems; but for one specimen that is found with a clear, faultless color and luster, many hundreds are found with different colors and faulty luster. It is the very rarity of these colors, combined with their quality, that makes them so valued. All are distinguished by their remarkably high hardness, which again adds to the value of the worked stone. They are surpassed in this respect by but one substance, viz., the diamond.

Spinel and corundum are not infrequently found in limestone and granite rocks, in the very place where they were originally formed; but most of the gems are found as washed and water-worn pebbles in placer gravels. The veritable land and home of the gems is the East Indian Island of Ceylon.

Of quartz, opal, and chalcedony, all of which are but different forms of silica, I need hardly speak. They are so common and occur in so many hundreds of different forms and colors, and places and uses, that they are more or less familiar to all. Opal differs chemically from quartz in containing a little water, while chalcedony is a mixture of the two. As I have just said, they occur in every conceivable color, and are very hard; the peculiar hexagonal shape of quartz crystals is certainly familiar. The precious varieties of quartz, and also of opal, furnish gems of a lower order, while the use of chalcedony under the names of onyx, sardonyx, carnelian, and heliotrope, for ring-stones, seals, medallions, and the like, is very common. But by far the most important occurrence of quartz is as a rock-constituent, in which form, associated with feldspar, micas, and hornblends, and in the form of sandstone, it makes up a very considerable proportion of the entire solid crust of the earth.

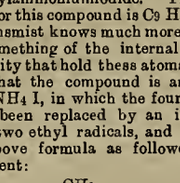
Pyrites.

We come next to the silicates or combinations of silica acting as an acid with the alkalies—potash, soda, lithia—and the alkaline earths—lime, magnesia and alumina. The heavy metals are excluded as essential constituents from these minerals, but iron in particular is very commonly present as an accessory constituent.

Many of these minerals are characterized by very complicated chemical composition; indeed, silicon seems to play the same part in the inorganic world that carbon plays in the organic world. It is extremely interesting, however, to observe the unequal progress that chemistry has made in the study of these two different classes of compounds; the carbon and the silicon, the organic, or those which enter into the composition of animal and vegetable structures, and the inorganic, or those which enter into the composition of many minerals.

For reasons familiar to the chemist, the carbon compounds have been reduced to an order and system that form one of the greatest triumphs of modern science. In the matter of classifying the silicates, however, upon strictly scientific principles, we are still groping, to a great extent, in the dark. And again, the same differences exists with respect to the state of our knowledge of single compounds in the two different classes.

Take, for example, by no means an extreme case, the organic compound, monomythyldiethylisobutylammoniumiodide. The empirical formula for this compound is $C_9 H_{22} NI$; but the organic chemist knows much more than this; he knows something of the internal bonds of chemical affinity that hold these atoms together. He knows that the compound is an iodide of ammonium, $NH_4 I$, in which the four hydrogen atoms have been replaced by an isobutyl, a methyl, and two ethyl radicals, and he can rewrite the above formula as follows, showing this replacement:



With the silicon compounds, the case is far different; our chemical formulæ remain absolutely empirical; we can simply determine by analyses how many atoms of each element are present, and write them down in a formula without the least conception of the mutual relations of these atoms to one another.

The chemical symbol for schorl or black tourmaline is:

$$H_2 Fe_2 Al_4 B_2 Si_4 O_{20};$$

but exactly how these atoms are related to one another no one knows, and the same is true of most other silicates.

About 120 species are comprised within this order, and they are conveniently subdivided into four families:

Sclerites,
Zeolites,
Phyllites,
Amorphites.

The sclerites, by far the largest family (84 species), comprise all the hard, anhydrous silicates, and we shall find in this family all of the minerals which, with quartz, constitute the great mass of the known crust of the earth as it was originally formed. I have already called your attention to the leaching process to which the land is constantly subjected by atmospheric waters, dissolving out the soluble salts which find their way to the ocean. Now, we have among the sclerites the very minerals which are originally subject to this leaching, from the decomposition of which come these soluble salts.

(To be Continued.)

An Ice Locked Ship.

The loss of the *Jeannette* by ice crushing and the toilings of her crew upon the waters and snowfields of the cruel Siberian coast give heightened interest to the accounts of Arctic dangers. The latest news is that a portion of the survivors of the *Jeannette* expedition who succeeded in reaching the Siberian settlements, had cast their faces again northward in search for their companions who were thought to be leading a forlorn hope in the trackless ice and snow wastes adjacent to the mouth of the Lena river. It is to be hoped that the search may prove successful and the sufferers rescued.

The engraving on this page, which shows the *Corwin* in the grasp of the ice field, will give the reader some idea of the perils of Arctic navigation. The *Corwin*, it will be remembered, was first sent out by the United States Government, in 1880, to search for the *Jeannette*, and was ordered out on a second voyage, for a similar purpose, in 1881. Upon his return from the cruise, Capt. Hooper reported to the Secretary of the Navy the incidents of his voyage, accompanied by some drawings to show the perils into which he came and the geographical observations made. From this report we take the accompanying engraving and descriptive notes:

THE ARCTIC EXPLORING SHIP "CORWIN" IN A NIP OFF CAPE ROMANZOFF.

On the morning of the 15th we found ourselves utterly helpless, drifting with the pack to the southward and eastward about two miles per hour. At first this caused no uneasiness, but about 8 A. M. it was noticed that we were among grounded ice. We had only five fathoms of water, and many large pieces were hard and fast on the bottom. Coming in contact with some of these grounded pieces the vessel got some pretty sharp nips, which tried her strength. At one time she was lifted bodily up several feet, and held suspended for some minutes; coming in contact with one, "stern on," the rudder was forced over, the screw steering-gear carried away, and the wheel-chains parted. Happily the rudder-stock, which is of the best Oregon oak, stood the strain, although for a time it seemed as if nothing could save it.

With this experience of the danger to which the rudder was exposed, I saw the necessity of having it rigged so that it could be unshipped at short notice, and set to work accordingly. All hands piled sacks of coal on the forecastle until the vessel was tipped sufficiently to raise her stern and allow us to get at and split out the wood-lock. A piece of oak plank was secured across the rudder-head by means of four long iron bolts, in such a way as to keep the rudder from unshipping by the action of the seas, and to be readily removed should it become necessary. We next cut a piece on the apron the size of the rudder-casing, so that the rudder-head could go forward sufficiently to allow it to unship without removing the apron entirely, then rigged a pair of sheers and rove off a purchase, so that the rudder could be taken in, out of the way of danger, in a few minutes. On the 16th, we drifted helplessly in the pack all day. On the morning of the 17th, clear water could be seen, from the mast-head, to the northward and westward. At the same time a slight roll of the sea was perceived, indicating that it was quite a large space. After working toward it all day, we succeeded in reaching clear water in the evening, having made about four miles in 10 hours.

The *Corwin* thus escaped to fight the ice again another day. The *Jeannette* met a harder fate. For 18 months she was ice locked and her crew prisoners. Then she yielded to the crushing of the ice and her crew were forced to the perils and adventures of which a full account is to be given on the return of the survivors.

A delegation of Zuni Indians from New Mexico has gone to Washington.

CHICAGO **FRASER & CHALMERS,** ILLINOIS.

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, improved form. Bullion and Copper Moulds and Ladles, Litbarge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. P. Haggin for Giant and Old Abe Co., Black Hills also Corliss Pumping Engines, 26x60, for Hoisting and Pumping Works, for 2,000 feet deep. **Baby Hoists for Prospecting, 4 H. P. to 6 H. P.**

Wire Rope, Safety Cages and any Size and Forms of Cars. McCaskell's Patent Car Wheels and Axles—Best in Use.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois. New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail.

HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,750 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. BOILERS of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

THE CALIFORNIA POWDER WORKS.

Sporting, Cannon, Mining, Blasting and

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

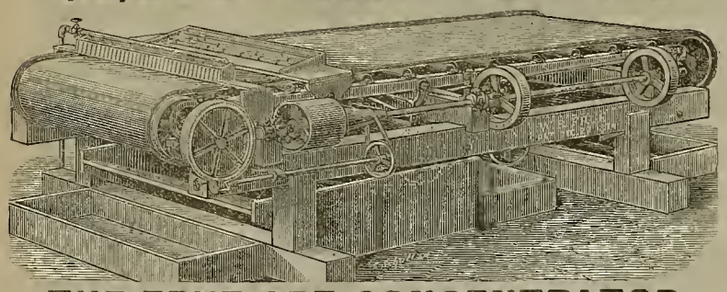
PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street - - San Francisco, Cal.

$1,000 CHALLENGE!



THE FRUE ORE CONCENTRATOR.

Nearly 300 are now in use, giving entire satisfaction. Awarded First Premium and Silver Medal at the Industrial Fair for 1880 of the Mechanics' Institute of San Francisco, Cal.

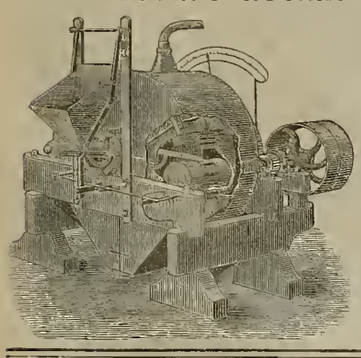
Saves from 50 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal; water required is less than in any other wet Concentrator; the power required per machine is less than one-half horse power; the labor required is light, one man on a watch can attend to sixteen machines.

We challenge any other Concentrator in use for a fair and impartial competitive trial, side by side, for stakes of $1,000 each, and we mean business.

☞A machine with all improvements can be seen in working order and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont street.

ADAMS & CARTER, Agents, Room 7 No. 109 California Street, S. F.

TUSTIN'S ROTARY PULVERIZING MILL.



WORKS ORE WET OR DRY,

And Feeds Itself Automatically.

Patented October 11, 1881.

One of these machines can be seen at the Ore Sampling and Pulverizing works of Hofmann Bros., No 415 Mission St., where it is working every day. Weight 5,000 lbs., heaviest piece 480 lbs.

Manufactured at the

TUSTIN WINDMILL, HORSE POWER AND PUMPING MACHINE WORKS.

308 Mission Street, S. F., Cal.,

By W. I. TUSTIN, Inventor and Patentee.

ENGINE LATHES IN SECTIONS.

Limit of weight for 25-inch Lathes, 300 pounds, For 17-inch Lathes, 150 pounds.

Standard and Special Machine Tools.

SAN FRANCISCO TOOL CO., No. 21 Stevenson St., San Francisco.

DEWEY & CO.'S

Scientific Press **Patent Agency.**

[ESTABLISHED 1860.]

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 252 Market St., S. F.

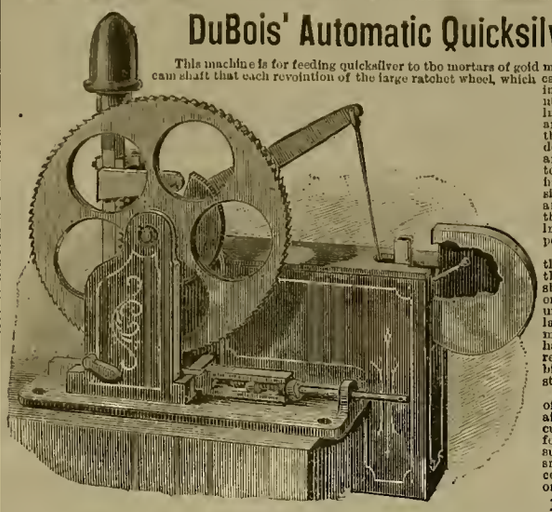
Manufacturers of
THE PATENT CHANNEL IRON WHEELBARROWS.
THE STRONGEST BARROW MADE. These Barrows are made by Superior Workmen, and of the best material. All sizes kept constantly on hand
SHEET IRON PIPE.
Lap-Welded Pipe, all Sizes, from Three to Six Inches. Artesian Well Pipe. Also, Galvanized Iron Boilers, from 25 to 100 Gallons.
Iron Cut, Punched, and Formed for making Pipe on ground, where required. All kinds of Tools supplied for making Pipes. Estimates given when required. Are prepared for coating all size of Pipes with a composition of Coal Tar and Asphaltum.
Office and Manufactory, 130 Beale Street, San Francisco.
SHEET IRON PIPE.

DuBois' Automatic Quicksilver Feeder.



This machine is for feeding quicksilver to the mortars of gold mills. It is so connected to the cam shaft that each revolution of the large ratchet wheel, which can be regulated to revolve once in one, two, three or four minutes, as desired, dips a small cup into a reservoir of quicksilver, and by a trip of the cam, empties the contents into a pipe leading down to the mortar, supplying an exact quantity at regular intervals, superseding the ordinary hand feeding, which is of necessity subject to great irregularity, and liable to neglect. It renders the amalgamation of all the gold in the pulp equally certain and perfect.
The mechanism to produce this depression and elevation of the cup, is driven by the cam shaft, similarly to the self-feeders, over which so much ingenuity has been expended to regulate the delivery of ore to the mortar. As it is to be desired to have the ore go in constantly and regularly, so it is equally desirable to have the mercury fed constantly and regularly.
A chief point of excellence of this machine is, that it allows the quantity of mercury which would be otherwise fed in mass, in one hour, to be subdivided into a number of small portions, and fed almost continuously; *i. e.*, from every one to four minutes.
Price, complete, $100.

For Sale by **WHITNEY & MARSHALL,** Sole Agents
22 & 24 Fremont St., San Francisco.
Dealers in Iron, Steel, Hardware and Mining Supplies, Wrought Iron Pipe and Fittings, Pump Columns, Wire Rope, etc. A large stock of Boiler, Plate and Sheet Iron of every description.

MOREY & SPERRY,
MANUFACTURERS OF
Gold and Silver Grinding and Amalgamating Machinery

HOWLAND'S PULVERIZER Takes the Place of the Cumbersome Stamp Mill and can be put up in one day ready for work.
IT HAS BEEN FULLY PROVED AND TESTED.
It weighs complete, 7,000 pounds It costs $1,500 ready for the belt Will crush one ton per hour of hard quartz that will pass through a 40-mesh screen. The wear is less than in the stamp mill. Its wearing parts are plain castings and can be dropped into position in a few moments, as shown by the letters A, B and C, no bolts or keys are required; it can be set upon the floor of a mill with no expense for foundations, and can be used to crush and work in charges or continuous. It will amalgamate either gold or silver ores, making a simple, cheap and effective mill, it requires twelve-horse power.
Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores Chloridizing Furnaces, Retorts, Rock Drills Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies Iron Work complete for Wood Frames, also
SPERRY'S WROUGHT IRON FRAME FOR STAMP MILLS.
☞Great saving in time and money over the Wood Frame. It is made complete with Wrought Iron Frame ready to put upon the foundation. We construct Mills with Stamps weighing from 350 to 900 pounds for Gold and Silver Ores. Wet or Dry Crushing Mortars.
MOREY & SPERRY—Warerooms, 92 and 94 Liberty St., N. Y.

LEFFEL'S IMPROVED WATER WHEEL.

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

From the official list of U. S. Patents in DEWEY & Co.'s SCIENTIFIC PRESS PATENT AGENCY, No. 22 Market St., S. F.

FOR THE WEEK ENDING FEBRUARY 21, 1882.

253,907.—ANIMAL TRAP—Alex. Andre, Bakersfield, Cal.
253,914.—TESTER FOR EXPLOSIVES—G. S. Dean, S. F.
254,011.—EMERY WHEEL—M. Hofstad, San Leandro, Cal.
253,927.—TENSION BRACE—Aaron Lawson, Gilroy, Cal.
253 930.—HORSESHOE—William Leed, Oroville, Cal.
253 936.—GRAIN SAVING ATTACHMENT FOR SEPARATORS—Neil McLean, Watsonville, Cal.
254,071.—BOOT—R. Thompson, S. F.
253,903.—WATCHMAN'S TIME DETECTER—H. J. Wenzel, S. F.
253,964.—STATION INDICATOR—H. J. Wenzel, S. F.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

TENSION BRACES.—A. Lawson, Gilroy, Santa Clara Co. No. 253,927. Dated Feb. 21, 1882. This tension brace consists in a wire or other flexible rod eo twisted at its middle as to form a double loop somewhat in the form of the figure 8. The ends of the wire project in opposite directions and at right angles with the loop, and are provided on their tips with screw threads. These threads are formed on one end to make a right-hand screw and on the other a left-hand screw, so that when screwed in place, they draw in opposite directions and pull tight on the central loop, which locks itself. The use of this brace is confined to articles the joints of which are liable to separate and need holding together. It may be used on hedsteads, chairs, or tables, etc. In any available corner one of these braces may be screwed and its projecting loop act as a hat-rack or hook or peg on which to haog articles.

HORSE-SHOE.—Wm. Leech, Oroville, Butte Co. No. 253,930. Dated, February 21, 1882. Tbie invention relates to the class of horse-shoes the object of which is to spread or expand contracted hoofs. It consists in two sides pivoted at the front center to a toe-plate, said toe-plate forming a hearing or support for a peculiar spring which lies thereon, and whose ends embrace the rear ends of the sides, whereby its tension is exerted at the ends. The beneficial object is further accomplished by the position of the nails in the shoe, whereby the outward pressure is brought to hear to the best advantage.

GRAIN SAVING ATTACHMENT FOR SEPARATORS.—Neil McLean, Watsonville, Santa Cruz Co., Cal. No. 253,936. Dated, February 21, 1882. This grain-eaving device for thrashing machines consists in the details of construction of a supplemental attachment to a straw carrier, whereby the straw is stirred and agitated as it leaves the carrier, so the grain mechanically entangled in the etraw may eecape and he recovered.

ANIMAL TRAP.—Alexander Andre, Bakersfield. Dated, February 21, 1882. No. 253,907. Tnis is a trap for gophers and other hurrowing rodents, and it is made in such a manner that the gate is less liable to become choked, so as not to close freely. A peculiarity is that a little slide makes the tube dark, so that no light ehall make the mole or gopher suspicious. The trap is eaid to have heen a very successful one.

A FEW days ago, in what is known as the "Old Walker Porphyry Claim," near Shingle Springs, El Dorado county, parties etruck a "pocket," from which they took a considerable amonnt of ore that paid them $250 to the pan, and were working quite a large vein that was averaging $10 to the pan, when the water rushed in and drove them out.

THE Bristol *Times* is in receipt of a letter from Cherry Creek in which the writer advises the Bristol and Pioche people not to go there in search of work, as nearly everything ie shut down. He statee that though the Star mine is being worked that there are more men there now than can find employment.

QUITE a number of Comstock miners are making arrangemente to go out along the line of the Carson & Colorado railroad this spring, as soon as the weather becomee eettled, for the purpose of prospecting and working in mines already located.

DURING the quarter ending Decemher 31st the Ophir, Crown Point, Belcher, Consolidated Imperial and two other mines produced 20,611 tons of ore, valued at $310,704. This is the smallest quarterly yield of the Comstock mines in many years.

AN immense "blow-out" of copper ore is found on one of the highest peaks of the Wasatch range in Utah, assays from which show 25% of copper, with from $7 to $8 of gold and silver to the ton.

Recent Contributions to the California State Mining Bureau.

[Furnished for publication in the MINING AND SCIENTIFIC PRESS by HENRY G. HANKS, State Mineralogist.]

[CATALOGUE.]

Graphite—Wood River, Idaho. Mr. Hailey.
Marble, Water-worn—Bed of the Tuolumne river. Lewis Costa.
Gold Quartz—Gold Blossom mine, Crater hill, near Ophir, Placer county, Cal. R. L. Dunn.
Compressed Asphaltum Paving Blocks—L. L. Robinson.
Amethyst—Lake Superior.
Garnets Detached from Garnetiferous Mica Schist—Found at the mouth of Stickeen river, Alaska. (See Nos. 2328 and 3812.) Laura E. Crane.
Copper-Stained Quartz—In which there is a cavity containing two perfect crystals of cerargyrite or horn silver, surrounded with bright metallic silver. A very rare and beautiful speciuen. Sierra Madre, Arispe, Sonora, Mexico. C. J. Pilsbury.
Fibrous Bituminous Artificial Stone Block for Street Pavements—Manufactured by the Cosmopolitan Paving and Asphaltum Company, and donated by Robert Skinner.
Crystallized Sulphur—Twenty miles north of the Humboldt station, C. P. R. R., Humboldt county, Nev. H. W. Faust.
Slab of Mica Schist with Garnets—Mouth of Stickeen river, Alaska. Donated by W. J. Buswell, Wrangle, Alaska, and brought down by Lieut. Commander Henry E. Nichols, of the steamer *Hassler*.
Murchisonia bicincta, Hall—Lower silurian fossil, Trenton limestone, Watertown, New York. D. S. Marvin.
Crinoidal columne—Upper silurian fossil, Ohio. D. S. Marvin.
Orthis occidentalis—Lower silurian fossil, Trenton limestone, Watertown, New York D. S. Marvin.
Modiolopsis modiolaris, Con.—Lower silurian fossil, Loraine shale, Watertown, New York. D. S. Marvin.
Petraia corniculatum—Upper silurian fossil, Niagara Gr., Ohio. D. S. Marvin.
Rhynchonella increbescens, R. Capex—Lower silurian fossil, Trenton limestone, New York. D. S Marvin.
Tridesia (Camarella) Sp. (?)—Lower silurian fossil, Trenton limestone, New York D. S. Marvin.
Murchisonia subconica (?)—Lower silurian fossil, Trenton limestone, New York D. S. Marvin.

Bucania bidorata, Hall (Bellerophon bidorsatus)—Lower silurian fossil, Trenton limestone, New York. D. S. Marvin.
Chetetes lycoperdon (Monticalinora lycoperdon)—Hemispherical and ramose forms, lower silurian fossil, Trenton limestone, Watertown, New York. D. S. Marvin.
Strophomena Sp. (?)—Lower silurian fossil, Trenton limestone, New York. D. S. Marvin.
Trematis Sp. (?)—Lower silurian fossil, Trenton limestone, Watertown, New York. D. S. Marvin.
Orthoceras arcuilratum, Hall—Lower silurian fossil, Trenton limestone, Watertown, New York. D. S Marvin.
Orthoceras tuseptum, Hall—Lower silurian fossil, Black river limestone, Watertown, New York D. S. Marvin.
Palæsrca Sp (?)—Lower silurian fossil, Trenton limestone, New York. D S. Marvin.
Strophomena rhomboidalis—Lower silurian fossil, Trenton limestone, Champlain, New York. D. S. Marvin.
Placer Gold—Hoosie Bar, Middle Fork of American river, eight miles from Auburn, Placer county, Cal. T. L. Flanagan.
Crytolites compressus, Con.—Lower silurian fossil, Trenton limestone, Watertown, New York. D. S Marvin.
Orthis vanalica, Hall—Lower silurian fossil, Hudson river group, New York D. S. Marvin.
Leptæna sericea, Sow—Lower silurian fossil, Trenton limestone, New York D. S. Marvin.
Heliophyllum Halli, Edwards & Haime—Devonian fossil, Hamilton period, Ohio. D. S. Marvin.
Illenus crassicauda, Wahlenberg—Lower silurian fossil, Trenton limestone, New York D. S. Marvin.
Phytopsis cellulosum, Hall—Lower silurian fossil, Bird's Eye limestone, Watertown, New York. D. S. Marvin.
Bathotrephis succulens, Hall—Lower silurian fossil, Trenton limestone, Watertown, New York. D. S. Marvin.
Patent Compressed Paving Tile or Slab—Asphaltum base with cement top. Robert Skinner.
Iron Ore (Magnetite)—Solid Iron Mine, Indian district, Mono county, Cal. D. P. Tarpy. Analysis by Faulknan & Reese: Peroxide of iron, 93.0; silica, 7.00; total, 100.00; graphite and sulphide of copper, traces.
Favosites niagarensis, Hall—Upper silurian fossil, Niagara period, New York. D. S. Marvin.
Amboncychia amygdalina—Lower silurian fossil, Trenton limestone, New York. D. S. Marvin.
Endoceras proteiforme, Hall—Lower silurian fossil, Utica shale, New York, D. S. Marvin.
Orthoceras junium, Hall—Lower silurian fossil, Trenton limestone, New York. D. S Marvin.
Soapstone or Steatite—Cut in the form of bricks and of the same size, to be used as substitute for fire-brick, Lewis, Mariposa county, Cal. R. M. Collins.
Natural Bamboo—Cut of a Very Large Bamboo or Concretion Strongly Resembling the Same—Near Tholame, San Luis Obispo county, Cal. J. Z. Davis.
Sandstone Concretion Resembling an Obscure Fossil Fish—Near Tholame, San Luis Obispo county, Cal. David Russell.
Glass Model of the Guadalupe Quicksilver Mine—Santa Clara county, Cal., made by Chas. T. Healy, who is the originator of the idea and presented by R. B. Thayer. This is a new and very effective mode or showing the underground workings of a mine.
Miniature Glass Model of the New Almaden Quicksilver Mine—Santa Clara county, Cal. Made and presented by Chas. T. Healy.
How and Rifle and Undercurrent—Wm. H. Howland.
Photograph of "Gorilla Niger"—Male, from a specimen in the museum at Lubeck, Germany. Jas. Behrens.
Photograph of Gorilla—Male and female, from specimens in the museum at Lubeck, Germany. Jas. Behrens.
Photograph of "Gorilla Gina"—Female and young, from specimens in the museum at Lubeck, Germany. Jas. Behrens.
Photograph of the Mammoth, "Elephas Primigenius"—Restored from measurements from the bones in the Royal Museum at Stuttgart, and data afforded by the St. Petersburg one. Prof. Henry A. Ward.
Vertebræ of Whale—Monterey whaling station. J. Z. Davis.
Rib of a Whale—Monterey whaling station. J. Z. Davis.
Jawbone of a Whale—Monterey whaling station. J. Z. Davis.

IRA S. PARKE, a well-known mining man of Virginia, Nev., dropped dead on Montgomery street last week. He had come to this city to attend the funeral of his brother, Francie A. Parke, who was killed the other day at Emery station, Alameda, hy heing run over hy the cars. He wae 54 years of age and one of the pioneers. He was one of Nevada county's leading citizens in early days, and was one of the first eettlere in Virginia City. He huilt the old Gould & Curry mill there. A brother of the deceased is a memher of the firm of Parke & Lacy, dealers in mining machinery, Noe. 21 and 23 Fremont street.

THE EUREKA QUARTZ MINE CASE.—This mine liee near Hornitos, Mariposa county; some time since the owners desired to file an application for a patent, which was refused by the Register and Receiver of the land office at Stockton, on the ground that the application embraced a portion of caeh entry made by Mrs. Delilah Scroggins. The caee was appealed, and the Hon. Commission at Washington has suetained the decision below, and ordered a hearing, to determine the character of the land.

Naturalists' Directory.

Collectors in the various departments of natural history find that they can aid each other greatly hy exchange of material. One who is interested in the work, asks the PRESS to copy from Casino's Directory a list of the names of California collectors, not claiming that it is complete, hut stating that those mentioned are willing to correspond and exchange material with others in the same line of study. We publish the list to facilitate correspondence and exchange, and thus eerve our readers who have leaning toward studies in natural history:

Ca ifornia Collectors Who Will Exchange.

Geo. W. Warren, Ferndale, Humboldt Co., botany, ferns, etc.
Mary E. P. Ames, Auburn, botany.
Rev. F. H. Wales, Dutch Flat, Placer Co., mineralogy.
Charles L. Anderson, M. D., Santa Cruz, botany, algæ.
Melville Atwood, Santcliff, geology. Special branch, inclosing, or wall rocks of metalliterous veins. Exchanges in speciality.
Mrs. K. F. Bingham, Santa Barbara, botany.
Frank E. Blaisdell, Poway, San Diego Co., entomology (local). Exchanges in ecology and coleoptera.
Mrs. S. G. Blaisdell, Poway, San Diego Co., ferns.
S. Bluthner, Lockeford, San Joaquin Co., coleoptera.
S. D. Bradstow, care Wells, Fargo & Co., S. F., paleontology, mineralogy.
Elisha Brooks, 1725 Sutter St., S. F., ferns.
Mrs. A. E. Bush, Curator State Normal School Museum, San Jose, conchology, mineralogy, algæ.
Miss Jennie R. Bush, San Jose, entomology.

Prof. Milo H. Gates, Green Valley, El Dorado Co., botany.
John H. Russell, San Jose, Santa Clara Co., exchanges Pacific coast shells for those from any part of the world.
James E. Waltham, San Diego, conchology, algæ. Offers all specimens found in San Diego or northern part of Lower California.
F. V. Hopkins, M. D., East Lake, Lake Co., mineralogy, geology
Lewis Locke, 926 Jackson St., S. F., ornithology.

A RAISE IN ORE PRICES.—Another break occurred last week in the price of ore, hy a material advance in rates hy the Boston and Colorado works, which has been followed hy the other huyers. The old price was a deduction from the New York quotations for fine silver, of 10% and $20 per ton. The new price first deducte 9% for ore carrying less than 100 ozs. per ton; 8% for ore hetween 100 and 200 ozs.; 7% for ore between 200 and 300 ozs.; 6% for ore hetween 300 and 400 ozs., and 5% for all ore carrying over 400 ozs. Under this list 400-ounce ore ie worth $22.60 more per ton than under the old price; 100-ounce is worth $2.26 more; 200 ounce, $6.78 more; 300-ounce, $13.56 more, and 1,000-ounce, $56.55 more. The Golden and Valley works pay 30 cents per nnit for each nnit of lead when the lot aesays over 10% lead and less than 100 ozs. of silver per ton. Tnis list will make the hoys feel happy and should stimulate production.—*Georgetown (Col.) Courier.*

FRUIT VS. VEGETABLES.—One of the latest theories advanced is, that apples are more nutritious than potatoes, and in Cornwall, England, workmen say they can work hetter on the fruit than on the vegetable.

THE Arizona *Star* says: Almost $12,000,000 of treasure were sent out from this so-called harren conntry. This year we promise the world $25,000,000 in gold, eilver and copper.

The Governor Declares Saturday a Legal Holiday.

SACRAMENTO, March 1.—The following proclamation has been issned by Governor Perkins:

WHEREAS, The question of Chinese immigration is of such vital importance to the welfare and best interests of this State, and as a hill is now pending before Congress to prevent the further influx of this class of people, and believing it to be the almost unanimous wish of the citizens of California that said hill should become a law, I have been urgently requested to declare Saturday, the 4th day of March, a legal holiday, that it may be made the occasion for one universal demonstration, conveying to Congress and to our Eastern hrethren the deep interest which inspires us to check this evil and stop this curse of slavery. This request is made oy a large and influential class of merchants, and by both the great political parties, and influenced by the same motives, partaking of a kindred spirit with them, and seeing the time has come for the exercise of the great, harmonious and simnitaneous effort to rid the State of this evil, I, George C. Perkins Governor of the State, do by the authority vested in me, proclaim Saturday, March 4, 1882, a legal holiday, and ask that in the several cities and localities of the State such demonstration he had as will show the feeling of our people in this question.

GEORGE C. PERKINS.
Governor State of California.

News in Brief.

THE electric light has found its way into India. At Calcutta the public gardens are lighted hy it, and the Elgin mills at Cawnpore also are.

THE House Committee on Invalid Pensions on Friday received a petition asking that the widow of ex-President Polk he put on the pension rolls.

LIEUT. DANENHOWER hae heen forhidden to start for St. Petersburg nntil the weather gets warmer. The remainder of the survivors of the *Jeannette* will start without him.

TWENTY-FIVE female doctors, who took part in the military operations of Russia in 1877, have heen decorated by the Emperor with the order of St. Stanielaus of the third class.

SENATOR MILLER introdnced a bill on Friday appropriating $175,000 for construction of steam vessels for the revenue marine, adapted for service in the waters of the North Pacific.

THE English iron masters of Middlesborongh have adopted the resolution of the Scotch iron masters at Glasgow, to prolong the six months' agreement restricting the manufacture of iron.

THE Stanislaus *Wheat Grower* says that most of the telegraph poles hetween Oakdale and Stockton have heen honeycombed hy woodpeckers.

A DISPATCH from Constantinople says: The mohilization of 150,000 troops is projected, in view of the probahle complications in Bulgaris, which make neceseary the occupation of the Balkans.

A COLONY of 220 Missourians contemplate settling near Benton, Montana, and it is reported that two colonies, one of 500 Scotch families, and the other of 400 German families, will locate near Glendive.

A PARTY of 150 English tourists, en route to the National Park, Montana, will reach the end of the Northern Pacific track early in the summer. They have contracted to pay $30,000 for transportation hetween that point and the park.

A MEMBER of the Horticultural Commission states that the orchards of Alameda county are more extensively infested with destructive insecte than the orchards in any other county in the State. This statement ronses considerable opposition.

B. B. HOCHKISS, the Americsn who invented the revolving cannon, has received the decoration of the Legion of Honor from the Frenoh government for his services to that country, and the Danish government has given him the Cross of Denmark.

THE work on the Atlantic & Pacific railroad eastward from Mohave is going forward as rapidly as circumstances will admit. It is reported at railroad headquarters, that the rails are all laid for a distance of 4,200 ft. The constrnction gang is eight miles out, grading and preparing the roadhed, and rnnners and snrveyors are ahead of the graders.

WITH one of the trains which went East this week was a car containing 25 sea lions, consigned hy A. C. Rohison to Charles Richie & Brother of New York for transportation to Europe. The animals were captured off the Santa Cruz Islands, and are of all eizes. They will he placed in crates, and from time to time will he delnged with water from a hose to preserve them in good condition.

THE tunnel to tap Eagle lake is now in 200 ft., and the preeent force is pnshing it at the rate of about 35 ft. per week. The entire distance to he pierced is ahout a mile and a half, and the work will prohahly he completed hy noxt fall, when the now harren wastee of sagehrush land of Honey Lake valley will be covered with water and made to produce in ahnndance.

THE Mntnal Union Telegraph Co., whoee system covers all the principal cities of the Union, except New Orleane and San Francisoo, is ahout to make a connection with thie ooast. Upon this point, saye James Gamble, General Superintendent of the company, well known here as formerly General Superintendent of the Pacific division of the Weetern Union Co.: "My nurpose in ooming here is to select a route for an extention of wires acroes the continent, and to see how each a proposition will he received hy the telegraphing puhlio, and what interest they will take in the matter. My plan is to huild a grand trunk line of three No. 6 wires hetween San Francisco and New York. This line will connect with all intermediate points.

PERSONS receiving a sample copy of the MINING AND SCIENTIFIC PRESS *with this notice marked*, are requested to examine the merits of the same, and consider fairly its claims for support, and if consistent, subscribe for the paper through the P. M. or agent delivering it, or otherwise. We shall send it, on trial, at the rate of $4 per annum for any period the reader may wish. Please notice our terms elsewhere, and if desired, send for further samples and information. Those who can circulate this No. further to our advantage are invited to do so.

A TURNED LEAF will point out the article supposed to be of special interest to persons receiving sample copies of this paper.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

BOUND VOLUMES OF THE PRESS.—We have a few sets of the back files of the MINING AND SCIENTIFIC PRESS which we will sell for $3 per (half-yearly) volume. In cloth and leather binding, $5. These volumes, complete, are scarce and valuable for future reference and library use.

CORRESPONDENCE on mining and other subjects represented by this journal is solicited from all reliable sources. Send us information, early and often, if ever so brief.

BY TELEPHONE.—Subscribers, advertisers and other patrons of this office can address orders, or make appointments with the proprietors or agents by telephone, as we are connected with the central systemin San Francisco.

THE State Mining Bureau, No. 212 Sutter Street, is open to the public from 10 o'clock A. M., to 5 o'clock P. M daily, (Sundays excepted). Henry G. Hanks, State Mineralogist.

ANNUAL STATISTICIAN of 1882.—"It is the most complete and accurate work of its kind in the world."—*S. F. Call.* Address L. P. McCarty, 316 California st. Price, $4.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

G. W. MCGREW—Santa Clara county.
M P OWEN—Santa Cruz county.
B. W. CROWELL.
J. W. A. WRIGHT—Merced, Tulare and Kern counties.
JARED C. HOAG—California.

Press, Box 2361, S. F.

Sewing Machines.

Several first-class styles, good as new, will be sold at a bargain. Call on or address H. F. D., at this office.

Mining and Scientific Press.

THE MINING AND SCIENTIFIC PRESS is the leading mining journal in America, and enjoys a larger circulation among the more intelligent operators and workers in the gold fields of the world.

Established in 1860, it has firmly maintained its position as a reliable, progressive journal. The information given in its columns has saved millions of dollars to the practical miners, metallurgists, mill men, mine and shareholders on the Western side of our continent.

Among its contributors are the ablest and most experienced mining engineers, superintendents and practical miners in this country.

The PRESS gives a condensed summary of Mining News from the most important mining districts of the country.

New processes and methods of mining are described in its weekly issues. New mining machinery and improvements are frequently illustrated and explained in a manner to be of great value to all interested in mining.

As a scientific and mechanical representative of the Pacific coast it is decidedly popular, and a standard journal with the most thrifty industrial people of the Pacific States and Territories. Its authority is of the highest order, and its usefulness in its special sphere unrivalled.

Every public library, mining engineer, metallurgist, mining operator and intelligent mechanic and manufacturer, will find profit by its reading.

Subscription, $4 a year in advance. Sample copies postpaid, 10 cents.

DEWEY & CO., Publishers.
No. 252 Market St., San Francisco, Cal.

Business Offices and Sunny Rooms to Let.

We have some desirable rooms to let adjoining the offices of this paper which will be rented on favorable terms. Stair entrance, No. 252 Market St. Elevator, No. 12 Front St. Parties wishing offices, etc., will do well to call and see them. DEWEY & CO.

Dewey & Co.'s Patent Agency and Newspaper Offices.

Dewey & Co.'s Patent Agency and the business offices of the Mining and Scientific Press, Pacific Rural Press, Pacific States Watchman and the Fraternal Record are now orably situated at No. 252 Market Street. Elevator entrance, *No. 12 Front St., S. F.*

Canvassing Agents.

We want several canvassing agents who will make it their business to solicit subscriptions and advertising for our first-class progressive newspapers. Men of ability and experience can secure good pay and permanent employment. Send references and state your past occupation, etc., to the publishers of this paper.

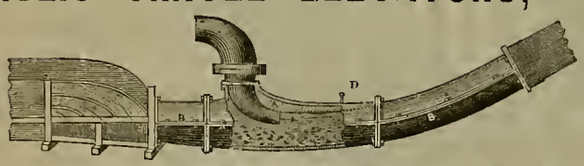
BUCKETS.

MINERS' HORSE-WHIM.

One Horse can easily heist over 1,000 pounds at a depth of 500 feet. The whim is mainly built of wrought iron. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The standard of the whim is bolted to bed-timbers, thus avoiding all frame work. When required these whims are made in sections to pack on mules.

HYDRAULIC GRAVEL ELEVATORS,



for working flat gravel mines that have no dump.

Sluices gravel and water up hill on an angle of 45°, and will run any kind of gravel that will run in a flume. Handles rocks as easy as fine dirt, and will raise as much material as the water will carry off in a flume on 6 inches grade to 12 feet.

No bedrock cuts, tunnels or drains required. Machine a sufficient drain itself, and the process of mining the same as any other hydraulic mine. Is now a practical success in various places in California and Oregon. Send for descriptive circular to

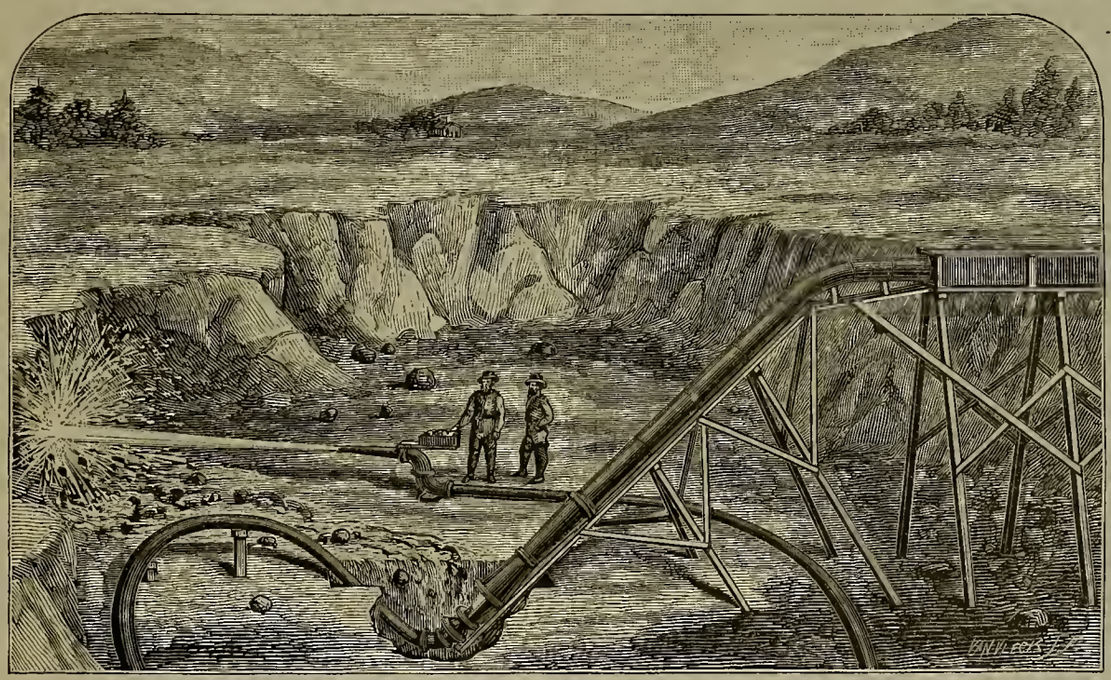
VOLUME XLIV Number 10.

Hydraulic Gravel Elevators.

These machines are simple in their conetruction, having neither helte, wbeele, pulleye, valves nor buokets, in faot nothing to need repair and nothing complicated. They oan be rnn by any one who can run a hydraulio mine. They sluice water and gravel up bill; work deposite that have only a ehallow fall nr dump; save the heavy expense of driving bedrock tnnnels, npen cute or drains; sluice gravel of any dimensione that will pase throngh a flume; and drain all eurplne water flowing from the gravel or on the bedrock; work ae well ae flumee having ten or twelve inchee grade, and will handle as mucb gravel in proportion to the wster need. The engraving ehows the manner of application of this style of elevator.

Their conetruction consists of an iron pipe having n horizontal ground eection and pipe leading therefrom upward at an angle of 45° to an ordinary open flnme lying above and extending beyond the pit, and into which the water and materinl forced through the pipe ie diecharged. Thie horizontal or ground eection ie conetructed with an open end back of or behiod the entrance of the pipe into which the hydranlic nozzel ie directed. The npen end of the ground section ie concave in shape, or a lower half eection of the pipe flaring outward and into which the gravel is elniced or washed by small outeide hydraulic gi n's, throrgh a hedrock flume leading to the Elevator throat or entrnnce; which ie eet below the surface of the bedrock as deep ae possible, whence it ie takeu up by the etream from the hydraulic nozzel fixed at the entrance of the aecending pipe, which, imping ing npnn the gravel, earth or other heavy material forced into the entrance from bebind, impele it forward and upward through tbe pipe to itı point of diecharge into the open flume above the pit or excavation, whence it ie carried away by a line of eluice boxes to a final point of discharge.



METHOD OF WORKING SHALLOW GRAVEL CLAIM WITH HYDRAULIC GRAVEL ELEVATOR.

Confined ae the material is within a tight iron pipe, it ie neceeearily impelled forward with the velocity of the etream iteelf, and ae eaoh particle of gravel or other material is directly acted upon by the full force of this strsam it ie necesenrily conoiderably pulverized by this aotion ae well as by the friction along the pipe in ite aecent, and this dieintegration ie so thorongh and conoiderable that long and expeneive outer flumee leading away from the pipe diecharge are rendered unnecessary.

From the impinging and frictional action of the water and gravel, it ie evident that the greatest amount of wear will be upon the ground section and at the point of curvature of the pipe, and that thie wear will be greater on ite under eection; consequnently the ground eection and curved portion of the pips are constructed in half eections, an upper and lower, with a flange turned out on each eids, eo that the two can be bolted together, and the lower half being worn can be replaced without trouble. In order to withstand thie wear the lower half section is made of the beet white or chilled iron.

These machines can he made of any capacity, and will handle any head of water used in hydraulio mining.

In operating the gravel elovator the primary object is, of conree, to have it perform all the work of whioh it ie capable, snd as it reqnires no more power to raiee a pound of gravel than to raise a ponnd of water, it ehould be tbe eudeavor to pipe as much gravel towarde and into ite entrance as is poesible, as it can rsrely he overloaded. It must be borne in mind that it coete as mnch time and money to run water through the elevator pipe ae it doee earth or gravel, and it requiree equally as mnoh power to raiee the one as the other. When the elevator is properly and advantsgeously eet and operated, the amount of material which can be raised or impelled through the pipe is governed and limited only by the volume and conoequent capacity of the water to osrry tbe material tbrough the outer discharge flume towarde it connection with the onter diecharge flume, thereby obvisting in a large degree the nmount of friotion encountered in the machinee before oonstructed, the radiue of the curvature of the pipe being greater; and further by incresoing the eize of the diecharge opening of the pipe gradnally ae it approaobes the outer open flume.

Theee machines, which are manufactnred in thie city by Joebua Hendy, are in uee in many placee on thie coaet, and have fulfilled the expectatione of purchaeere in enabling them to work ehallow auriferoue depoeite.

towsrd the dump.

It is estimated that 100 feet of hydraulic preeeure will lift 10 feet high; and ae high preseure worke better than low preeeure, 200 feet of preeeure will lift 20 feet high better than 100 feet will lift 10 feet; or whilst 100 feet of preeeure will only lift 10 feet, 200 feet will lift 22 fcet and 300 feet 40 feet. Therefore, with an available head of 300 feet the hydraulic gravel elevator will wash any depoeit 40 feet in depth.

It will be obeerved that eince the earth, gravel or other heavy material which paeses through the elevator pipe neceeearily occupies a certain portion of ite space, and dieplacee a proportionate amount of water, that, therefore, the volume of watsr required to impel the gravel, etc., forward through the pipe will not bs eqnal to the capacity of the pipe, that in fact, not more than one-half of such will he ueed, and that the remainder can he utilized in the mine through the hydraulic nozzele in driving the material towards and into the elevator.

Theee elevatore are built of any required dimsnsione and capacitiee, and many improvemente have recently been introdnced into their construction, which makee the form now manufactured euperior in every reepeot to those which have herstofore been ueed. Theee improvements conoiet in having a larger opening of the pipe at the ground section entrance, which diverges, or ie contracted at the upper end of the eection, thus coutracting the epace through which the material muet paee, and permitting a more direct action or impingement of the etream of water upon it; also in giving a more gradual inclination or upward grade of the pipe

Exhibition of Fossils.

At Mercantile Library Hall on Bueh etreet, in tbis city, ie now on free exhibition, a very large collectiou of csets and foseils, etc., by Henry A. Ward, of Rochester, N. Y. The exhibition is the best and only one of the kind ever seen on thie coaet, and it ie to be hoped it will be kept here through the liberality of eome individual. The collection ehould belong to the Acadeiny of Sciences.

Noticcable among the objecte ie a "reetored" counterpart of the great Siberian mammoth, the remaine of which were found in the ysar 1799, frozen in the ice hanke at the mouth of the river Lena, in Siberis. The skeleton stands in the museum of the Imperial Academy of St. Pstereburg. Alongeide etands the skeleton complste of an elephant of the present day.

Within the rail surrounding thie monster ie n cordon of caste or remaine of ite contemporary monetere. Among theee are the ekull and tueke of a mastodon of the pleietocsne age, exhumed near Newberg, New York; remains of a glyptodon, or moneter tortoiee, found near Uruguay, caet from the original in the muoeum of Dijon, France. One of the moet wonderful representatives of that period of animal mouetroeitiee exhibited here is the caet of a complete skeleton of the megatherium or moneter sloth. The structure of this skeleton denotes prodigioue etrength and a horrible aepect. Beeide these there are caste of skulle of the cavedwellers, the Neanderthal man and other prehistoric racee. The fac similes of the Puehlos and cliff-dwellings of Arizona and New Mexico are specially interesting. The exhibition is open to the public without charge, and no one ehould fail to visit it.

An Important Mining Decision.

Juetice Field, in bebslf of the United Statee Supreme Court, bas rendered a deciein in the csee of the St. Louie Smelting and Refining Co. vs. Kemp and Nuttall, which is of immenee importance to all mining intereete. Thie ie the oaee heretofore referred to as having heeu decided by Juetice Miller in the Circnit Court for Colorado, and taken to the Supreme Conrt on a writ of error for final review. The plaintiff relied for revereal of the Circuit Court judgment upon three grounde: Fiiet, an error in admitting the record of the proceedinge of the Land Office to impeach the validity of the patent issued upon them; secoud, an error in instructing the jury that a patent for a plscer claim eince the Act of 1870, eculd not embrace, in any case, more than 160 acree; and third, an error in instrncting the jury that the owner, by purchase, of sevcral claime muet take separate proceedings upon each ooe, in order to eustain a valid patent, and that it was not lawful for him to proeecute a single application upon a coneolidation of several claims into one, or for the land officere to allow euch an application and to iseue a patent thereon. Justice Field, delivering the decision of the Supreme Court, esid: "We are of the opinion that theee several gronnds are well taken aod that in eeoh particular the court below erred." He then proceeded to deliver a very able and remarkably exhauetive opinion, dieouesing all the various pointe raised, reviewing the entire hietory and purpoee of mining legislation, eetting forth the disastroueconcequences which would result from upholding the reversed deciein, and expounding the doctrinee which the Supreme Court will apply to all eimilar questione hereafter.

An Important Mining Suit.—The Southern Nevada Mining Co., whoee stock was recently lieted on tbe San Francieco Bosrd, have brought euit in the U. S. Circuit Court at Carson againet the Northern Belle Mining Co. to recover $600,000, the value of ore alleged to have beentaken from the Southern Nevada's ground. The new company have, by etipulation of attorneys on both eidee, had official eurveye made by competent eurveyore, and claim that they can prove to a certainty that over 10,000 tone of ore havs been taken within their linee. Their claim at Candelaria was formerly known as Chief of the Hill. Judge J. McM. Shaftsr is Preeident of the Southern Nevada, and R. E. Kelly, formerly of Careon, ie Secretary.

Additional mining pay-rolls for February work have heeu reported as follows: Yellow Jacket, $7,987; Crown Point, $16,019.87; Belcher, $9,375.37; Crown Point and Belcher joint ehaft, $2,356.50; Alta, $6,930; Benton, $3,540; Savage, $11,200; Con. Virginia, California and C. & C. ehaft, $11,303.75; Union, $14,478.

Moved by the tremendous storiee told of the mineral wsalth of New Mexico, a correspondent of the Chicago *Tribune* suggeste Baron Munchaueen for Governor and Eli Perkins for Secretary of that Territory.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Southern Arizona.

Dos Cabezas District.

EDITORS PRESS:—Although this mining camp has never had a "boom," and has not, either by newspapsr articlss or the efforts of effective, full-blown talkers, had as much done for it as some other districts which have richer surface ores, it will, notwithstanding, be heard of in future years, in connection with paying mines.

The Mineral Belt,

(Or rather series of mineral belts) covered by it is very extensive. Its northwesterly end is near Railroad pass, eight or ten miles northeasterly of Willcox station, on the Southern Pacific railroad. From thence it extends southeasterly about 20 miles, to Fort Bowie, its average width being eight to ten miles. The mountains it traverses belong to the Chirricahua rangs, which, at Apache pass, turns from a northerly to northwesterly course. Towards the westerly end of this deflected part of the range, a lofty mountain, with two distinct heads or peaks, visible from points 70 to 80 miles distant, gives the district its Mexican name.

These cabezas, or heads, seen from the railroad, do not look as if they were 120 to 150 ft. above the top of the rocky pile they belong to; but when one is at their base, they prove formidable towers. On the northwesterly side of these peaks is Railroad pass; on the southerly side, rather pleasantly located on a plateau considerably above the level of the valley, is the

Town of Dos Cabezas.

If the great expectations some persons seem to have in respect to the future of this town are to be realized, and its 320 acres of a townsite survey are to be all occupied by buildings, streets, avenues and squares, it will ultimately be a place of much importance. Irrespective of miners in the hills, the town has about 120 inhabitants. It has a hotel, three stores, four saloons, blacksmith and butcher shops, a feed-stable or two, a silent, five-stamp, shortive quartz mill, a good 10-stamp mill just finished, and several cattle corrals, the stock from which range on the contiguous slopes. The substratum is granite, and good water is found everywhere 30 to 40 ft. down. There is little or no dust in summer or mud in winter, and few places surpass it as to healthfulness. There are cooling breezes in summer which keep the thermometer generally, though not always, below 90° in the shade. Perhaps a trifle more of this breeziness is experienced in the spring and fall than is desirable, but then as there are not over 20 days of enforced idleness by bad weather in the whole year, there is no great reason for complaint. The old mail road between Arizona and New Mexico passes through the town, Tucson to the west and Silver City to the east being nearly equidistant—a little over 100 miles.

There is an express and post office, with daily mail, and a recently-started weekly newspaper, called the *Gold Note*, gives us the current news. The population is quiet and law-abiding, and only at times when an extra quantity of cow-boy slickens has been imbibed have we any noise or pistol shooting on our streets.

The Mineral Lodes

Are quite numerous, and some of them are very large. There is a massive east and west quartz vein, the croppings of which are seen from the town, two miles off. It is traceable for four or five miles, and is 100 ft. wide in some places, standing 80 ft. above the general surface. Most of this mass is barren, hard white rock, but there are streaks and veins in it of softer quartz, which carry from $5 up to $40 in gold. Whether these auriferous deposits will increase in average value as shafts go down upon them is something yet to be determined by persistent development. So far, no fair test has been made at sufficient depth to prove anything conclusively, but miners and experts are alike hopeful as to the future of the lode. There is evidently but one great ore channel at this point, although in several places it shows three or four seemingly distinct veins extending over a wide surface. The southerly or footwall rock is diorite, and the hanging wall talcose slate—bounded by a reef of porphyry on its northerly side.

To the north of this mineral zone the formation for several miles is a soft promising granite, covered on the ridges by trachytic porphyry. Here we find a belt of four or five lodes running east southeast and west northwest. They are large and heavily stained with copper. Some of them assay $20 to $40 in gold, a few dollars in silver and 12% to 30% in copper.

Another belt runs nearly due north and south, and has still larger veins. Some of them 100 ft. wide, with the same kind of ores, the assays in gold and silver going higher, however. A third belt has two or three north northwest and south southeast veins, similar to the others as to outcrop. No work of consequence has been done on these lodes in the granite, and all that can be said of them is that, with heavy ore croppings and promising assays, there is a good prospect of mines being found by development, which, if not very high in grade, will at least be extensive, and as true fissures, they will have the advantage of comparative permanency. On the northerly side of the aggregated mineral belts, also in granite, considerable work has been done of late on a series of white quartz veins carrying galena and other sulphurets in blotches and streaks. These lodes have improved so much by sinking on them that confidence in other ledges not yet worked upon has been strengthened. Some of them have good concentrating ores worth from $30 to $60 per ton, and gradually increasing in value with depth, though the despest opening is only some 40 ft.

The Silver Camp,

Lying toward the westerly end of the main belt, also in granite, has a number of small, very rich chloride veins. The ores on the surface were a good deal mixed with porphyry and clay, but 50 ft. down they have become compact and yield 9 to 12 inches of clear ore worth $80 to $300 per ton in bulk, though assays go up into the thousands. As the whole surface is seamed by small veins, it is thought, with good reason, that as depth is attained, large bodies of ore will be found. The work done on these veins has always been paid for by the yield in bullion, and now that a custom mill is ready to reduce their ores, several valuable properties are sure to be opened.

Closing Notes.

From springs and wells the necessary water for milling purposes can no doubt be obtained. Firewood is not plentiful, though there is enough to last for several years of active milling work. Ultimately we will have to rely on coal brought by rail to Willcox station, 15 miles off. If it is once demonstrated, as it no doubt will be, that we have extensive mines which will pay to work, we are sure to get final at moderate prices. Even if reduction works were erected near the railroad, a narrow-gange road to carry the ore to them would soon be provided.

CENDA.

Dos Cabezas, Cochise county, A. T., Feb. 27th.

A New Dry Ore Concentrator.

The dry ore concentration works of Messrs. Thurmond & Hamilton in Russell district, situated in the large stone building between the mouth of Illinois gulch and the stamp mill and wet ore concentrator of the Miners' Sampling Co., is now running. A visit to these works was made yesterday by a reporter of the *Register-Call*, who witnessed the treatment of a quantity of low grade ores from the Clifton mine, in the head of the south fork of Willis gulch. The ore is first thoroughly dried by a furnace, the drier being on an incline. After drying it passes through a Forster improved crusher; from thence the ore passes to Cornish rolls, and thence to a machine 14 ft. in length, 60 inches wide at the top and 7 inches at the bottom, which is set on an incline of 4 inches to every 12 inches. An improved fan blower 45 inches in diameter, capable of being speeded up to 1,600 revolutions per minute, sets at the bottom of the machine or air chamber, the latter having 14 different sets of graduated screens, commencing with those of a fineness of 100 mesh and ending with 16 mesh. The fine particles of mineral are collected at the head of the graduated screens. All ore not passing through a 16 mesh screen is elevated and carried back to the Cornish rolls. The gangue rock or waste material is elevated and passed outside of the building. The principle upon which the work is based is that of specific gravity, or rather a gradated air draft working in conjunction with gradated screens. The concentrated ore is drawn off in two sizes, which are sacked up ready to be sent to the smelters. Samples of the ores are made by means of automatic samplers attached to the gates of the air chamber. The concentration of the ore is controlled by the amount of mineral it contains.

It is claimed by the inventor that, as air is less dense than water, when the law of gravitation is invoked for the purpose of separating particles of metallic from earthy matter, provided that the rise of air can be as effectively and economically controlled and directed as that of water, being a more subtle and less resisting medium than water, these particles can be, and are, more readily stratified and separated than it is possible for them to be in water. The volume of air in the chamber is under control of the operator by means of a lever.

The motive power used is a 40-horse power steam boiler and a 30-horse power Bay State engine. The capacity of the works is 40 tons per day, which can be increased by adding another graduated air chamber, rolls, etc. The work executed thus far by Messrs. Thurmond & Hamilton has given satisfaction, although, for the most part, it has been experimental. With the modifications and added improvements recently made it is predicted that they will meet with that success in the treatment of low-grade ores that has been anticipated for them.—*Central City (Col.) Register.*

THE ÆTNA QUICKSILVER GROUP.—Machinery has been shipped to the Granville Quicksilver mine, near Pope valley, for clearing it of water, which troubles mining operations. A road is to be put through from the Napa Con., or Oat Hill mine, to the old Phœnix mine, opening up a highway direct from Pope valley to the St. Helena Mountain toll-road. The Ætna Mine boarding-house is run by the Snow family, late of Middletown. The principal mining is now being carried on in the Star Quicksilver mine. Some of the shareholders and parties interested will visit the group of mines embraced in the old Phœnix district this spring, when it is expected extensive mining operations will be entered upon, and the old camp be stimulated into new life and development.—*Cor. Calistogian.*

Miners' Lamps.

The New Tin Can (Davy) Safety Lamp.

At a recent meeting of the Manchester Geological Society, at Wigan, a very interesting discussion took place concerning miners' lamps, which is reported in full in the *Colliery Guardian:*

Mr. H. Hall, Her Majesty's Inspector of Mines exhibited and described specimens of the new tin can (Davy) safety lamp, which consists of an ordinary Davy lamp enclosed in a tin cylinder or lantern, perforated at the bottom for the admission of air and open at the top, the light given by the lamp passing through a square glass window on one side in one lamp, and through a circular glass passing all round the lamp in another. No doubt, Mr. Hall said, all who were present at that meeting were acquainted with the elaborate tests which had of late been carried out with safety lamps in that and other districts. These seemed to have proved indisputably that many of the safety lamps at present used were safety lamps only in name, and the days of their old friend Davy seemed to be doomed. He was, however, happy to be able to produce before them that day a Davy lamp improved in a certain way, which judging from the experiments that had been made, seemed to be the safest lamp that could be obtained. It had, he was told, been subjected to 1,800 cubic feet of explosive mixture per minute passing upon it, as well as to a variety of other tests, and during the whole of these tests it had never been found to fail. By simply placing an ordinary Davy inside a tin lantern, they had a lamp which was doubly locked, and the outer tin shield not only prevented any current of air affecting the lamp, but also provided an additional safeguard against accident, as in the event of a miner striking the lamp with a pick, the injury would be received by the shield instead of by the lamp itself. So far as his own experience went he preferred the lamp with one glass in front, because it could be more readily held in the hand without feeling the heat. So far as drafts were concerned, he had tried the lamp under most tremendous pressures of air without any material effect. These lamps had been introduced into Durham in thousands, as well as into the Seaham and other collieries. He hoped therefore that the Lancashire people, if they approved of the lamps, would not be slow to adopt them also. He did not know that any one could claim the invention; it was not patented, and it seemed to him rather as if some boy had had an ordinary Davy lamp, and had contrived the outside tin cylinder as a shield to keep his light from being blown out.

Mr. Wm. Smethurst said he understood Mr. Hall to state that the tin can Davy was an absolutely safe lamp. Under certain conditions it was, but he must take exception to the conclusion that it had never been known to fail. It was known to fail where the perforated holes were put too high up. If they were put too high up the air current would have much the same effect as upon an open lamp. One objection to the lamp was that being enclosed in a case it was in a perfectly still atmosphere, and the dust getting inside the lamp casing, covered the lamp, and the small light it gave was thus still further reduced by the covering of dust. The Mueseler lamp, if constructed in a proper form, would undergo the same test, and putting the Davy lamp into a tin case, as shown, rendered it comparatively speaking a safe lamp, taking care of course that the holes were not put too highup. If they took a Mueseler, and instead of a single disk, a double disk was placed for the chimney to rest upon, then they had a safe lamp. An objection had been raised to the Mueseler, that it it were held on one side it went out, but considering how they had to depend upon the protection of the glass, he thought this, instead of being an objection was rather in favor of the Mueseler. He thought the tin can lamp would be open to the objection that when the glass became covered with dust, the collier would try by some means to get through to see if he could not wipe the glass, whilst if they had glass all round they increased the liability of its being broken. Under any circumstances, however, they reduced the light to a certain extent. Something, however, ought to be done with regard to the lamps at present in use, and especially when they considered how unsafe the ordinary Davy lamps were with the present system of ventilation. The sooner government or they themselves took the matter in hand the better. He would, however, prefer that the government took the matter up, because no one man could do it in a district, as the men, if they did not care to use the lamp would leave the colliery and go elsewhere. If government would say that such and such lamps must be abandoned—he did not say which lamps should be used—they would have a better lamp. In the tin can lamps which had been shown it was essential for their safety that the perforated holes should be kept below the standards so that the current could not be brought against the gauze. They had Davy lamps at present in use in most of the collieries, which, taking into consideration how very short a time such a lamp was safe in an explosive mixture with anything like a high velocity of air current, were rather startling. And then their opinion as to the amount of gas required to cause an explosion had been considerably altered by actual experience. In former days 12½% of gas was considered the most explosive mixture, but from actual experience they found that 3½% was quite sufficient, and with coaldust 3½% would be enough to cause an explosion. So that if they would take into consideration how small a quantity of gas it took to cause an explosion it was essential that every effort should be made to bring forward a lamp which would be safe under these conditions, and which ought to be used. The lamp which had been exhibited was a step in the right direction, and it was the best method of making a Davy lamp safe.

Mr. William Pickard (formerly miners' agent in the district) said that, viewing the matter from a working man's point of view, he hoped that in considering the best safety lamp to be adopted they would not overlook the question of usefulness. The Davy lamp, he thought, was already quite dark enough to be put into the hands of a workman without surrounding it with further complications in the shape of a casing in which the dust would lodge, and still further impede the light. What they wanted was an invention which would secure safety and at the same time give the collier light; a lamp that would not allow the man to work in gas, but, in the second place, would give him light in safety. In the tin can Davy, he thought that while they were protecting from danger in one extreme they were rendering it liable to danger in another. He quite agreed that the Davy lamp, as at present in use, was, as had been abundantly proved, not safe; but he did not think that surrounding it with a tin cylinder, in the form that had been shown, was giving greater safety to the lamp, and, certainly, it was not giving greater facilities for light. From the working men's point of view, he would ask them not to take into consideration the use of these lamps in the Lancashire coal mines.

Mr. C. F. Clark was in favor of a lamp that went out immediately it came in the presence of gas. No lamp would be safe that did not go out in an explosive atmosphere, and, considering the dangers they had to contend with underground, he thought their attention ought to be directed to improving the lamp so that it might be made to go out immediately in the presence of gas. Any other lamp would be always liable to accident, however safe it might be. He thought a lamp that went out in the presence of gas would satisfy the workmen much more than by giving them one which would enable them to work in a mine half full of explosive gas.

Mr. W. Topping said he had long been of opinion that a Davy lamp, with the circular glass shield, was the safest lamp produced, and they had introduced the circular glass shield lamps into their most "fiery" mines. One objection to these lamps had been the liability to the breakage of the glass, but the one encased in tin, as shown by Mr. Hall, was a perfect shield from any current or draught in which the lamp might be placed. If it could be proved that the ordinary Davy lamp, placed in a tin can, could give out as much light as the Davy lamp unprotected, he should certainly say it was by far the most suitable lamp yet invented. A lamp was intended for light, but they wanted a lamp which would not only enable them to do their work, but which would also afford the means of determining the nature of the atmosphere with which they had to deal, and give them such light as would enable them to walk out of the danger. His experience, during the last few days, of the tin can lamp had been such as to convince him that it was one of the best lamps ever invented, and with regard to the dust, he had not seen, as yet, that it had been any defect. With the view of testing what current was likely to affect the lamp, he had allowed the full force of all the air coming down the pit to come in contact with the lamp, and the result had been to convince him that in any hurricane it would live.

Mr. Teale said this lamp had been in use in the pits of the North for some time, and he thought the tin shield was originally designed more with the view of protecting the lamps from injury. He thoroughly believed that collieries could be properly and well lighted, and, he might say, almost with perfect safety. They had only to get over some primary difficulties—arising, in some cases, from prejudice, and in others from custom—and he had no doubt they would have a better lamp in the mines. If the intention was to have a thoroughly safe lamp the tests to which it would be submitted should be stated, and then they might arrive at what they considered the best lamp for the purpose. He did not, however, think the tin can arrangement was so safe as it was imagined to be.

Mr. Wm. Smethhurst observed that if they had to have perfect safety in their mines with regard to lighting, then the enclosed Davy was fit only for the underground managers and the firemen who went to examine the places. It was not fit for an uneducated man; for such a man, let him by all means have a lamp that went out. The Mueseler could only be fired in one way. So long as the current kept straight in one way they could not explode the lamp; it could only be fired by suddenly reversing the current. If they had a double disc and narrow top to the chimney they would have a perfectly safe lamp.

THE Castle Doms mines are hooming and hoisting immense quantities of metal. These mines have made more money in proportion to capital expended than any other group of claims in Arizona.

THE Lodi mill, at Silver peak, is being moved a short distance, and will be put in running order in a short time. It has five stamps.

MECHANICAL PROGRESS.

Belting Leather.

In the manufacture of belting the selection of leather is of the utmost importance. The hides of grass-fed prairie cattle furnish a good material for belting leather, and these hides are, as a rule, superior to those of stall-fed Eastern cattle, the fiber being more compact and solid, and producing leather less liable to stretch. The best hides for the purpose are those taken from cattle four or five years old, as the hides of animals of that age have not been subjected to the stretching and shrinking, resulting from changing condition, as have the older ones, and the leather is consequently more apt to remain straight. In fact, perhaps the best and cheapest belt in the world is made from the hide of a four or five-year-old bullock that has been fed on grass, the hide thoroughly bark-tanned, and a long time allowed for the process.

The belt manufacturer has one important disadvantage to contend with. Along that portion of the hide over the backbone, full or humpy places are frequently found, caused by the shape of the animal, and it is often difficult and sometimes impossible to make them flat; hence the belt retains the unevenness through its centers, and refuses to properly hug the pulley. The following rules are given for the avoidance of this difficulty.

In making a wide double belt the hides should be cut along the middle, the back edges should be outward and the side edges inward, a side center piece being inserted in order to break joints widthwise. In three-ply belts the same method may be adopted. The advantages gained are the following: The edge portions of the belt being firm, solid and unyielding leather, and the middle portions of looser texture, it is reasoned that after running a short time the middle will "give" to the higher part of the pulley, and the edges will not only hind down, but will also afford a lateral support which will relieve the tension of the middle and insure an even bearing the whole breadth of the belt. Again, when the middle of the belt becomes stretched and allows the edge portions to bed themselves down to the pulley, the working strain will be distributed over the entire width. Lastly, it will, no doubt, be noticed that cutting down the middle of the hide enables the currier to work out, with the greatest ease, any uneven or full places, the surplus being cut away in the process of straightening.—*Boston Jour. of Com.*

Practice vs. Theory.

Mr. James Abernathey, in an article on this subject, says: It matters but little how practical the inventor, designer or builder may be, his efforts are deemed theoretical until they have been tested at work. This is especially true with makers of machines combining a number of different and simple elements or principles. All may be satisfied that each of the elements independent of the others is well understood and all right, but are not satisfied that the combination will work all right until it has been tried, and well tried. After a trial has been made and proven successful, all ideas of theory in connection with it ceases, and it is accepted as practical. Other machines, built precisely like the first, and for the same purpose, are accepted without question. And there is really no question about the practicability of larger or smaller machines built on the same general plan and for the same purpose.

It is true that practical men make mistakes. All classes of men do that; but it is a thousand times safer to have a good practical knowledge than have none at all. And I would like to say right here to all young beginners, as they learn practically, to also contract a habit of thinking; learn to trace the workings of causes to their effects, and effects back to causes. In other words, become students, and continue to be students. If you run into difficulties, think and study yourselves out. It will pay you in the future, and be of inestimable value to mankind. The writer has always been a student, and is a student to-day, but has been by no means as studious as he should have been; much valuable time has been wasted, and an ignorance of many things of which he should have been well informed now stares him in the face.

A NEW USE FOR SPENCE'S METAL.—The material known as Spence's metal is composed principally of iron pyrites, and has the properties of melting at a low temperature and cooling very rapidly, thus enabling it to be cast in gelatine molds, by which process the most elaborate carving can be accurately reproduced. A perfectly sharp casting can be obtained by pouring this metal at a temperature of 250° F. into a gelatine mold which melts at 90°. Chilled at once, the metal forms a hard skin before the gelatine has time to melt. The heat of the metal will, after some time, melt the mold, too late, however, to injure the casting. When taken out of the mold, the metal has much the appearance of black wedgwood, and is susceptible of the same amount of polish. Statues and bas-reliefs of any size can be cast with accuracy, and the finest work, such as the plate of a steel engraving or the carving of a Chinese card-case, can be exactly reproduced. Its capability of withstanding exposure to the weather renders it very suitable for the decoration of architecture.

Close-Fitting Fire-Doors.

It is a somewhat common notion that air-leaks around the doors on a boiler front, or through the brickwork, or in the flue-cover plates at the back end of the boiler, do not amount to very much in the cooling effect which they produce. It may be hard to say, in exact figures, what this cooling really amounts to, for the measurement of the quantity of air thus needlessly admitted is by no means an easy thing. The area of the crevices may be readily enough determined, but to get the actual or the average velocity of the flow through them is far from a simple process. A useful comparison may sometimes be made of this leakage area with actual clear area between the grate bars, and in some cases that could be cited this proportion would be found surprisingly large.

The utmost care should be taken when test trials are to be made, that all such leaks of cold air are stopped (and most properly, too), in the same way that search is made for steam-leaks about an engine, and for air-leaks into a condenser. It is too often the case, though, that when the test trial has been finished this rigid care is laid aside, apparently upon the ground that as the high results of a closely watched test can never be reached in everyday work, therefore no special pains whatever need be taken, either for careful fixing or for exact conditions of apparatus.

The fact cannot be denied, however, that there is money value, and in a year's time a good deal of it, in the maintenance of the very best conditions of things, in all the particulars of which the close-fitting fire-door may be taken as the type.

A boiler is fired for the purpose of heating the water in it, and every ounce of air that passes into the boiler-setting, through leaks of any kind, involves a waste as much as though an equal weight of sand, or any other useless material, were poured in and heated up. This leakage of air, it must be remembered, is constant—all the time running—and even a slight opening in the wall or against one of the front plates, will pass wastefully in the course of a week enough air to represent a very snug little sum in the bills which must be paid for coal. This leakage flow of air into a boiler furnace, it should be remembered, is a very different thing from the admission of air above the fire by an exactly regulated slide or similar device, although even this admission is too often recommended and made in ways that are simply absurd, and which lead to as palpable waste as leaky doors or rickety walls can ever cause. This branch of the subject is supposed by some to be quite complex, and is not often dismissed with few words.

A NEW-STYLE STEAM PRESS FOR FORMING AXES.—The *Daily Times*, of Chester, Pa., says: "The large steam hammer or press at the Beatty Axe Works, on Second street, this city, H. B. Black, proprietor, mention of which was made some months ago in this paper, is now about completed, and is expected to be in working order in a day or two. It is an immense piece of machinery, weighing 13 tons, and capable of making a hatchet, adze or broad-axe in a remarkably short space of time. Its working is somewhat complicated. Dies are used according to the shape of the tool desired. In these dies a piece of iron of the proper weight is put, and by intense pressure the iron is reduced to the desired shape. By an ingenious arrangement the iron is "steeled," that is, the required piece of steel is welded to it by pressure from four directions. It is again placed in the die and repressed and the "eye" punched. A man then takes it, points it, and dresses it up ready for the market. This machine is expected to turn out 24 dozen hatchets per week, and a man could not make more than 10 dozen in the same length of time. It is also used for cutting iron, in which it is the means of saving much labor. A heavy knife is put upon the machine, and it will make a clean cut through a piece of cold iron 2¼ by 1½ inches. There is no other press in the country like this one. It was invented and patented by William Evans, employe in the works, and gives promise of becoming a valuable piece of machinery about an edge-tool works, on account of its speed, which always cheapens productions. Mr. Evans has been a long time perfecting it."

SLIDE VALVE AND LINK MOTIONS.—It is a somewhat remarkable fact that the common slide valve and the link motion, both having been introduced in the early days of the steam engine, remain substantially as they were originally invented. We have, it is true, the Joy and the Marshall valve gear, which are being introduced and may in time supersede the usual style of link motion, but such is not at present the case. Again, in the case of the D slide valve, circular valves have been employed to some extent, and are considered by those who have employed them as giving better results than the ordinary D form. Also we have the Allen valve which is considered to be superior to the common form, and which, strange to say, although an American invention, is probably more in use in English than in American practice, having been applied to many English locomotives. The numerous rotating slide valves that have been devised have universally proved failures, and other forms of valve in which a circular surface is employed require much more care and attention in order to keep them steam tight than is the case with a flat surface.—*Industrial World.*

SCIENTIFIC PROGRESS.

Power of the Microscope.

The magnifying power of the microscope has been brought by modern improvements to about 100,000 diameters. There is a difficulty in determining the exact degree of magnifying power exerted, the only method of comparison being "the apparently barbarous one of placing one eye to the instrument and looking at a finely graduated plate of known dimensions, and looking with the other eye at a common foot-rule at a proper distance for ordinary sight, and with practice bringing the objects together in the field of view."

It has been found that in microscopic observations the use of the electric light makes it possible to illumine at least 500 times stronger than with gas, and that in other important respects the new light is far superior to the old. By what is known as Clevalier's method, the light is separated by its difference in refrangibility so that the heat rays are nearly excluded, and only the luminous rays thrown on the objects to be examined.

Bold as the attempt may seem, microscopists have undertaken, by means of the extremely minute observations they are now able to make, to estimate the size of the ultimate elemental particles or atoms of which all matter is composed. This measurement has not as yet, it is true, been made with exactness; but it is claimed to be well ascertained that these ultimate particles cannot be over one twenty-millionth of an inch in diameter. The startling belief is expressed that the common house-fly is able to see and distinctly recognize these inconceivably minute particles, its eye having been found equipped with a peculiar circular muscle, unknown to early entomologists, which enables it to so change its focus and apply its lenses as to attain this incredible visual power.

The most skillful microscopists, with their most effective instruments, are able to examine the form, color and nature of monades one hundred-thousandth of an inch in diameter, which is a long way off from the delicate precision above indicated, but still can hardly be called a coarse or clumsy way of investigating material phenomena. The best of human eyes, without artificial aid, can see no objects much smaller than one three-hundredth of an inch in diameter.—*Mechanical News.*

What is Materialism?

Materialism is a form of belief, or mode of thought, which in all things prefers to rest on the evidence of the broadest impressions of physical sense, and which suspects, where it does not deny, the reality of aught that cannot be brought to the test of sense impression. It objects to advancing beyond the primary elements of consciousness; and any steps which it takes in the region of mental or moral phenomena, it takes grudgingly, and with a constant dread lest it should be led to recognize as real anything that cannot be *felt* as we feel sticks and stones. The materialist has to live as other men, and, where his theories are not at stake, he will use ordinary human language as freely as others. He will talk of hope and fear, of love and hatred, of ambition and apathy, of honor and disgrace, of character and motive and principal, as if he knew what he meant, and as if the words he used answered to certain realities of human life. But once touch his theory, and he will seek to drain these words of all meaning, or else fall back upon vague talk about "modes of matter."

Materialism is the refuge of minds that have been immaturely freed from spiritualism, or perhaps we may more fitly say, spiritism. By spiritism we mean that undeveloped condition of the mind in which hypothetical existences are required at every turn to account for observed phenomena, in which the mind cannot bear to be left alone with facts. The child learning to walk holds by its mother's finger; the mind learning to think uses such hypotheses as it can construct, and for physical acts it frames spiritual antecedents. The child who thinks it can walk before it really can, and leaves its mother's finger, finds itself compelled to creep along by the wall. In like manner, the materialist who has let go his spirit hypotheses, is compelled to creep along by the wall, to rest upon something *hard*, in order to steady his steps. Divert his attention, and he will walk for awhile with his hands free; but remind him where he is, and he totters back in a moment to his tangible support.—*Popular Science Monthly.*

MAGNETIC BRICKS.—It was lately observed by Herr Kepner, at Salzburg, in the Tyrol, that some old bricks had an attractive or repellant force on a compass. From each of eight varieties of clay in the neighborhood two bricks were molded, and one of the two in each case was baked. The unbaked bricks had no action on a magnetic needle, but seven of the eight baked bricks proved polarly magnetic. Some further experiments have been made by Herren Kell and Trientl. Particles of powder of the magnetic bricks adhered to a steel magnet. Breunerite, mica-slate, argillaceous iron-garnet, chlorite and hornblende were, before heating, unmagnetic, but intense heating produced a magnetic polarity, the axis of which seemed to be perpendicular to the plane of stratification.

Animal Combustion.

Within every living organism there are two opposing forces. The "vital force," which produces all the phenomena of life, holds the material elements in unstable relations, against their will, so to speak, and it is antagonized by the natural chemical affinities of the elements, which tend to break down the organic compounds and re-arrange the elements in more stable form. This decomposition takes place in some degree during the life of every organism, and when life ends, or when the vital force ceases to act, it rapidly destroys the structure.

The waste matter resulting from this disintegration must be immediately removed from the body of the living animal, otherwise it clogs and poisons the system. The method of its accomplishment is one of the most admirable functions of the animal economy. To remove the effete matter in the natural liquid or solid state would be very exhausting; consequently it is burned, and the gaseous products of its union with oxygen are then easily carried away. Literally speaking, this makes a furnace of the body of every animal; and the most pressing and ceaseless demand of the system is for oxygen to support its fires. Respiration is hence an absorbing and excreting process, whereby oxygen is received and carbonic acid and water removed. It thus becomes a measure of the amount of combustion.

In the "cold-blooded" animals, respiration bears a direct proportion to the activity and the heat of the body, as the former causes a metamorphosis and waste of tissue, and the latter always aids decomposition. The fact is one of common observation. It is well illustrated in the quickened breathing of a tired animal, and in the almost entire suspension of respiration in the hibernating state. The respiration of a "cold-blooded" creature is increased by artificial heat. In extremely hot weather, frogs may have to leave the water entirely, and fishes come to the surface to procure air. Reversely, frogs can be kept for years in a state of suspended animation by a low temperature, and revived by warming. Some low animals can survive freezing or drying for an indefinite time; and, under such conditions, the waste of the tissues must be entirely suspended. —"*How Animals Breathe*," *in Popular Science Monthly.*

ELEVEN SCORE ASTEROIDS.—The number of asteroids that have been discovered is now 220. Recent researches by Herr Hornstein (communicated to the Vienna Academy) appear to prove that the number of those with a diameter of over 25 geographical miles is extremely small, and that probably all such were discovered before 1859. On the other hand, the number of asteroids with a diameter less than five miles seems also to be very small, at least in the parts of the asteroid zone next Mars; in the outer regions next Jupiter there may be a more considerable number of these very small bodies. Most asteroids seem to have a diameter between five and 15 miles. The average number of asteroids with a diameter of 5 to 10 miles discovered annually within the last 20 years is about three; the number of those of 10 to 15 miles diameter about 16. Thus, should no telescopes more powerful than the present ones be used in future search for those bodies, we may expect but a moderate "find" of asteroids with diameters under 5 or over 15 geographical miles, while a considerable increase of those with diameters of 5 to 15 miles may be looked for. It further appears that in the case of the smaller asteroids of 5 to 10 miles diameter the improvement of optical instruments and star maps has resulted in no great increase of annual discoveries in the inner zone; such an increase is observed only in the outer zone. Within certain zone limits there is an increase of the average number of yearly discoveries with the time and with distance from the sun, but beyond the outer limit this increase ceases.—*London Times.*

COMET SEEKING.—The number of comet seekers is so few, compared with the amplitude of the tracts of sky to be explored nightly, that it is probable that many celestial visitors escape detection. Several observers may be simultaneously at work upon one region, while larger areas may be left entirely unexplored. To prevent such unintentional waste of time and labor, the *Science Observer* suggests a mapping out of the heavens and an allotment of special tracts to particular observers, who shall agree to explore them nightly. This wise plan is accompanied by a condition which, it strikes us, is not so commendable; and that is, that each recipient of a tract of sky for comet hunting shall agree not to trespass on the preserves of the rest of the comet seekers. It is quite proper to pledge a man to work his own field thoroughly, but if he has time and inclination to do more, why shouldn't he? And what is more likely to spur on a comet seeker to the ample and thorough sweeping of his sky tract as the thought that if he misses a comet his neighbor may chance to find it, and so convict him of negligence or incapacity?

ADJUTANT-MAJOR GAUMET, of the 27th Regiment of France, has patented an instrument which he calls a "telelogue," for signaling purposes. The signals consist of the letters of the alphabet and figures silvered on a dead black ground, and these are illuminated at night by lamps with strong reflectors. A powerful telescope is the receiving instrument. For signaling to a distance of two and a half miles the whole apparatus need not weigh more than five pounds.

Diablo, Feb. 24th, $8,200; Contention Con., $19,030; Silver Reef for February, $52,676; Hanauer, March 1st, $5,500; Horn Silver, 1st, $30,000; Tiutic, 3d, $4,546; Starr Grove, 4th, $4,000; Horn Silver, 4th, $10,000; Bullionville, 4th, $6,438; Barbee & Walker, 4th, $1,705; Hanauer, 4th, $2,250; Nevada, 4th, $3,100.

ALTHOUGH none of our mills are running at present, says the Tuscarora *Times-Review*, work in the mines progresses as usual, and considerable ore has accumulated. In a number of our mines leases have been taken by miners who do not care to fool away their time idling about town. Some are taking out rich ore, and all appear to have excellent prospects ahead.

The Mining Share Market.

There is not very much to say about the mining share market one way or the other, for just at present it is attracting very little attention. The committee appointed by the San Francisco Stock and Exchange Board to consider the practicability of the members of the Board engaging in the business of buying and selling grain on commission, submitted its report at a meeting of the Board on Wednesday. The report recommends the organization of a new association, to be known as the "San Francisco Grain Exchange." This organization is to have a membership of 150, and its purposes are to be "to provide and maintain suitable rooms for a Grain Exchange in the city of San Francisco, to adjust controversies between members, to establish just and equitable principles, uniform usages, rules and regulations, and standards for classifications, which shall govern all transactions connected with the grain trade, to acquire, preserve and disseminate information connected therewith, to decrease the risks incident thereto, and generally to promote the interests of trade, and increase the facilities and the amount of the grain business in the city of San Francisco." The organization will have its own caller, and he entirely distinct from the San Francisco Stock and Exchange Board.

The following shows the financial condition of leading mines on the 1st inst: The following mining companies had each on hand March 1st in the sums stated: Alpha, $1.974 72; Best & Belcher, $4,699.17; Chollar, $17,561.27; Challenge, $320.39; Exchequer, $12,884.04; Gould & Curry, $19,368.80; Hale & Norcross, $2,164.16; Imperial, $7,485.29; Julia Con., $1,066.34; Justice, $15,593.96; Occidental, $6,604; Potosi, $3 487; Sierra Nevada, $5,973.35; Savage, $957.21; Silver Hill, $1,330; Utah, $3,457.64. The following mining companies had an indebtedness March 1st: Belcher, $39,000; Bullion, $20,431; California, $3 549; Crown Point, $544 50; Mexican, $22,713.53; Ophir, $22,079.54.

Of the flooded mines on the Comstock, the *Enterprise* of the 8th, says:

The water day before yesterday did not reach a point ninety feet above the 2,300 level, as reported yesterday morning. It would have been at the point mentioned day before yesterday, at four o'clock in the evening, had it continued to rise as rapidly as it was rising in the morning, hut it apparently reached some level in which there were many large openings. Yesterday morning it was within eighteen inches of the highest point reached on the occassion of the former big flood, and last evening it was eighty-three feet above the 2 300, or seventeen feet above the 2,200, and rising slowly. During the past twenty-four hours it has risen hut five feet. It is supposed that the water may now be filling ground in the Overman, probably on the 1,900 level, which, owing to the difference in the levels of the two mines, it is thought it may have reached.

Where the water will stop it would be hard to even guess. To reach the Sutro tunnel it must come up to within 1,513 feet of the surface. The pump is still kept running at five strokes per minute. Seven stroks per minute are fonnd to hold it, which is some gauge of its strength. As yet no arrangement has been made for a combined effort toward pumping it out. The Belcher is the only pump besides the Yellow Jacket, that can he brought to hear on it. In addition, the Yellow Jacket company could run their hoisting tanks.

Meetings and Elections.

Golden Chariot, March 6th. Trustees—John Rosenfeld, L. Gerstle, J. Clark, R. T. Carroll, Henry W. Seales, Archibald Borland and Louis Rosener. The act of the President in leasing the mine to Richard Bennett, Oct. 31, 1881, for a period of six months, was ratified and approved, and the Secretary authorized to notify the lessee that the Co. would resume possession of their property at the expiration of the lease. The Secretary's report shows that the receipts from bullion during the past five months were $25,408 25, and the expenses $19,267.67, leaving a balance now on hand in bank of $6 340.58.

Lucky Hill Con, March 6th. Directors—E. J. Baldwin (President), W. A. Lampe (Vice-President), F. A. Henke, M. J. Newmark and W. A. Green. H. A. Unrich, Secretary.

Father de Smet. At the recent annual meetiug the receipts for the past year were shown to have been over half a million dollars, and the expenses $314,666. Dividends of $25 000 each were paid in March, April, May, June, July, Novemoer and December. On the 1st of January, 1882, there was a balance on hand of $42,824, and the clean-up for the first half of January was $18,437. Dividends were paid on the 1st of January and 1st of February 1882.

Sutro Tunnel Co., March 6th. Directors—C. W. Brush, David Cahn, F. F. Son, Wm. Irvine, William Johns, Hugh Marshall and John Meyer. The following officers were appointed for the ensuing year: C. W. Brush, President; William Irvine, Vice-President; Pelham W. Ames, Secretary; Lazard Freres, Treasurer; and Thomas, Superintendent.

Potosi M. Co., March 7th. Directors—A. K. P. Harmon, C. L. Weller, William Norris, J. H. Dobinson, J. D. Fry President. A. K. P. Harmon; Vice-President, C. L. Weller, Secretary, W. E. Dean, Superintendent, I. L. Requa.

Hale & Norcross M. Co., March 7th. Directors—Chas. T. Bridge, George Congdon, S. Heydenfeldt, W. S. Hobart, W. Kohl, E. Norton, Walter F. Sell. President, George Congdon; Vice-President, Walter E. Sell; Superintendent, D. B. Lyman; Counsel, S. Heydenfeldt; Treasurer, Nevada Bank; Secretary, Joel F. Lightner.

New Incorporations.

The following companies have been incorporated and papers filed in the office of the Superior Court, Department No. 10, San Francisco:

CALIFORNIA PIANO MANUFACTURING CO.—March 6th. Capital, $200,000 Object: To manufacture, sell, rent and hire pianos and other mus cal instruments, yesterday filed articles of incorporation with the County Clerk. Directors—Eugene Soule, Henry F. Marsh, John W. Stewart, F. W. Von Reynegom, John Henderson, Jr.

LESTER M. CO.—March 6th. Location: Arizona. Capital, $2,000,000. Directors—Alexander Herman, Claude L. Smith, Simon Silverberg, H. W. Tucell, Sam Hart.

A SIXTEEN-MULE team pulled out from Winnemucca for Silver City, I. T., recently, which, together with the freight wagons attached, covered 150 ft. in a straight line. The train was laden with 125,000 lbs. of merchandise.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

ALPINE.

ISABELLE.—Monitor *Argus*, March 6: The Isabelle Gold and Silver M. Co. is kept constantly running on ore from the Stella mine. It is reported that the ore is much richer and not so base as heretofore in the mine. The mill has been on ore the last few days that assays from $300 to $400 per ton. We are confident the Stella is a rich mine and we sincerely believe Mr. Chalmers has a boranza. The wood business in Alpine the present season is one of its leading industries. Seven wood camps are in full blast, and about 10,000 cords of wood are being cut for the spring drive to be run down the Carson river this spring.

AMADOR.

GOVER.—Amador *Dispatch*, March 4: The Govsr mine, which has been closed down for a year or more, started up on Monday last, and they are now hoisting the water out of the shaft. The Hazard, Potosi, Seston and Maryland mines are still working. The Potosi mill was started up this (Thursday) morning. The Phœnix reduction works also started up to-day.

SOUTH SPRING HILL.—Amador *Ledger*, March 4: J. R. Treglon has been in San Francisco for two weeks past in the interest of this company. In all probability the mine will be started up soon

SEATON.—The first clean-up was made this week, but as yet we have not heard the result. There is rock enough to keep the 20-stamp mill running steadily Sulphurets from this rock are unusually rich. They yield about $180 per ton; but a month's run will not produce more than between 5 and 6 tons. It is intended to sink a new shaft immediately. D. T. Davis has resigned the superintendency, and at his suggestion Mr. Simons, from Tuolumne, has taken charge.

FROM VOLCANO.—The quantity of rain which fell during the latter part of last week and first of this, with strong indications of more to come, has encouraged our miners to some extent in the belief that there will be a good though short season for them yet. At the tunnel things are booming. The water supply is not sufficient to enable them to work continuously, but is a great deal better than it has been any time during this winter. Their great reservoir fills up about 19 times in 24 hours which, with the assistance of the hydraulic, makes the ground disappear quite rapidly. Another giant is being put up, to be supplied with water from the Jackson ditch, which is in thorough repair as far as Tiger Creek. At the Downs mine a clearing is being made around the new shaft, preparatory to putting up the hoisting works. Water is the propelling power at the Golden Gate mill now, notwithstanding only enough can be obtained to run 5 stamps. The Grass Valley claim is in full blast, with all the water they know what to do with, and plenty of rich ground upon which to use it.

CALAVERAS.

SOUTHERN MINES.—*Mountain Echo*, March 1: Work is progressing finely in the Black Oak mine, and big results may be expected soon. Bill West & Co, are working their mine near the Great Western. The lead is small but prospects well Lindsay & Co., are working steadily in their mine drifting for the main lead, with every prospect of a good strike when they get to it. Work on the Bald Hill mines is still going on, under very unfavorable circumstances, however, owing to the bitter cold and disagreeable weather. Findley & Co. have just started two arastras. They have on hand about 30 tons of ore taken from the Doc. Hill mine, and which has the appearance of being rich. The lead is about 6 ft wide at a depth of less than 20 ft.

MONO.

MACHINERY FOR THE GREAT SIERRA.—Bodie *Free Press*, March 2: The work of hauling the new machinery for the Great Sierra mine up the mountain is now in progress. It is expected that it will take from 15 to 20 days to get this machinery to the mouth of the tunnel. There are several pieces, the heaviest of which weighs at least 2,200 lbs. Owing to the grade, this machinery must be taken up by the aid of a block and tackle, thus making the progress very slow. One bench is 1,250 ft high and another one about 700 ft. The angle is 45° and the entire distance is 6½ miles. Fifteen men will be employed in the work. No small expense will be entailed in forwarding this enterprise, and it is to be hoped those who are expending the money will be duly rewarded.

BODIE ITEMS.—*Free Press*, March 7: The Bodie, just now, is a mine that people are closely watching, and many inquiries are made regarding the rich vein of ore in the west crosscut under winze No. 6. When this vein was cut, a short time ago, it was about 0 inches wide. Now it has widened out to 12 inches, and the ore is of a very rich character. But 2 or 3 tons are being crushed each week, but the average assays run up to between $900 and $1,000 per ton. The chances are good for this streak of ore widening out and developing into a bonanza similar to the one struck in the Bodie in 1878. The formation of the ground and the location are certainly favorable. A strike just at this time would stimulate mining and set the whole chain of mines in motion again. Business would increase, dozens of men be put at work, and the town would boom as in the early days. But we must be patient and let pick and blast uncover what must be hidden beneath the surface. The Standard Con. is prospecting energetically, and the 1000 level is looking much better now than formerly. The hullion shipments come up to the average, and the regular dividend (No. 39) has been declared and payable on the 13th. The Noondays are producing enough ore to keep the large mill running, and, in the meantime, prospecting is active. The Oro Co. is crosscutting on the 714 level. As warm weather approaches the outside camps are beginning to regain activity. In Lundy there is talk of erecting a mills during the coming summer, and Aurora is happy in possessing a 20-stamp mill, which will be kept running for a year at least. Aurora has mines, but no money; good prospects, but not enough energy. A great many Bodie people are interested in Sweetwater, and the outlook for that young district is of the most encouraging kind. Considerable money and a great deal of labor will go into the district this summer. Altogether, Mono county is looking up, and the favorable indications are steadily improving.

NEVADA.

SCOTIA MINE.—Nevada *Transcript*, Feb. 5: The New York *Mining Record* asks of the *Transcript* what is being done with the Scotia mine at Grass Valley and what are the chances for its stockholders. The Scotia is still idle. The shaft is filled to the top with water, the pumps and all underground appurtenances having been removed to the surface. After sinking a compartment shaft about 150 ft deep the water became uncontrollable and heavier machinery was procured. After this machinery had all been set and put in motion the mine ran a short time, when it closed down. From the 150 level and at various other points drifts were run but it is said none of the ore found assayed high enough to encourage the stockholders in expending any more money. The hoisting works and all the buildings still remain, the property being in charge of a watchman. Various rumors have been afloat about the mine starting up in the spring, although our reporter cannot obtain any definite information to warrant such rumors. The ledge it is said did not come up to the expectation of the prospectors, and that seems the long and short of the business. The management paid all its indebtedness before stopping work

COPPER MINES.—*Tidings* March 5: We learn from Capt. Bitford, who came up from Spenceville on Tuesday, that the copper mines in that section are now looking much better than recently heretofore. The gentleman informs us that the San Francisco copper mine is turning

out about 38 tons of pure copper per month. A dividend was recently declared.

MINING BUSINESS.—*Tidings*, March 6: There is a considerable talk in mining circles here about the starting up of the Massachusetts Hill mine in the spring, as negotiations are now being made to that end in San Francisco. Everybody who is acquainted with the Massachusetts Hill property have the utmost confidence in its richness. There is a bright outlook for lively times here this season, in a mining way.

STEAM STARTED.—Steam was started this afternoon on the Ontario mine, located on the lower Colfax road near the Blodget ranch. The mine has been bonded by Messrs. Richardson & McGriff, who propose to develop the ledge. Hoisting works are now complete on the property, and a perpendicular shaft will be put down immediately.

BARS OF BULLION.—*Herald*, March 7: The Citizens Bank yesterday forwarded to Thomas Price, assayer, San Francisco, two bars of gold bullion from the hydraulic claim of Duncan & Co. The bars are valued at $4,100, and are the result of a recent clean-up at the above claim, which is located at the Rogers ranch, on American hill.

OPERATIONS IN VARIOUS QUARTERS.—*Transcript*, March 7: Work having been abandoned through the new shaft on account of the heavy flow of water, the Derbec Co. are principally confining their operations to the old workings. The ear mules have been taken down into the bowels of the earth again, and the stable rebuilt for their accommodation. It will probably be months before these faithful creatures see sunlight again. The making of a drain tunnel is undoubtedly necessary to the prosperity of that claim. It contains large deposits of rich gravel, but the enormous expense of raising the water by steam power precludes the probability of anything better than Irish dividends.

PLUMAS.

GREEN MOUNTAIN.—Greenville *Bulletin*, March 2: During the weeks that the Green Mountain mills have been idle the machinery has been thoroughly overhauled and everything about the mills and mine put in the most complete working order. The mills will be started up by the end of the week. About 3,000 tons of milling ore are reported stored in the mills, mine dumps and chutes. Tunnel No. 5 is in about 3,000 ft, two-thirds of that distance being on the vein; it has now cut the third and main greatore chimney of the mine and opened it over 250 ft through pay, the face still in excellent ore. The upraise, 400 ft through ore in the sulphuret ledge has just made connection with tunnel No. 4 The work has been rapidly pushed during the past 5 months and now its completion places the mine in a better developed condition than at any former time in its history; the amount of ore added to the reserves of the mine is very large. The mine promises a handsome production for the future.

THE SOUTHERN EUREKA was the last mill that had to yield to the scarcity of water, but it had to hang up at last. The enforced idleness was but brief, however, for on Saturday the mill was started up again, and is now running as usual. The wise course of the superintendent in arranging to pump the water back after it had once passed the batteries and make it do duty over and over again enabled him to keep the mill running long after all others in the district had stopped. With the amount of ore in sight in this mine it is strange that the company do not increase their milling capacity.

GOLD STRIPE.—It is reported that the Gold Stripe mine is showing a good ledge of ore in its western part which is being rapidly opened. Considerable depth has been attained; the necessary connections with the tunnel will be made, and in the early spring work will be sufficiently advanced to commence milling. It is very much to be regretted that the excellent and extensive plant should be standing idle, and we hope to see it working to its full capacity before long.

KETTLE.—The Kettle mine has been thoroughly drained, the timbering of the main levels and stopes strengthened, and the ore in the face of the old levels will be sent to the mill as soon as the letter can be started up, which is expected to be done before the week ends. The amount of work accomplished by the present company is very large, and the developments made, as greater depth is attained, well sustains their hopes. Sufficient ore is now exposed in the mine to ensure steady runs for the mill for a considerable time.

ANOTHER PROSPECT.—Plumas *National*, March 4: Hallahan & Co., who have been running a prospect tunnel on the west side of Minnehaha creek, have found bedrock and report says got a fine prospect. Their tunnel was too high, and a shaft was sunk from it over 50 ft in depth. The work develops a fine bed of blue gravel and blue clay, and pan prospects show that the gold is there. This is something entirely new, and an important strike, as the channel is undoubtedly very extensive. They are putting in pipe to furbish good air and will soon show up what is in the claim.

NEVADA.

BATTLE MOUNTAIN DISTRICT.

REPORTED STRIKE.—Lander *Free Press*, March 3: It is reported that a big strike has been made in old Battle Mountain. John Kinney and Jake Schram are the lucky finders. We have seen specimens, but do not know the exact location. Hope the strike is as good as the specimens indicate.

CANDELARIA DISTRICT.

NORTHERN BELLE.—*True Fissure*, March 4: The character of the ground in the main shaft is very hard, and some time has been consumed in timbering, in consequence of which but 9 ft have been added, making the total depth of the same 84 ft to the 27th inst. The daily yield of ore has been about 54 tons. Both mills are running steadily. Mill No. 1 is still engaged half time on Mount Diablo ores. Bullion shipments for the week ending March 2d, $14,591.20. Total shipments on February account, $60,293.07.

MOUNT DIABLO.—The general appearance of the mine is much the same as at the date of last report. The stopes above the east drift on the third level continue to turn out the usual amount of ore, and the stope below the north crosscut from the west drift on the third level shows improvement. The stope below the north crosscut on the second level, near the center of the mine, continues to open very well, assays of the ore broken going from $124 to $434 per ton. The stope on the first level is looking very well. Bullion shipments on February 25th, $8,263.87; shipments on February 28th, $9,283.02; total shipments for February, $47,187.23.

EAST MOUNT DIABLO.—The main drift is progressing finely, and for the past week has been advanced 14 ft, making a total distance of 25 ft east of the company's line. The appearance of the ground is good, and everything points to a fine development at an early day.

GEN. JACKSON.—Work was resumed on Wednesday on this mine in the east incline shaft. Some first-class ore is being extracted, and the ore dump has already grown quite large.

PRINCESS.—Some active work is now being done in sinking the shaft. Three shifts are employed, and good progress is being made in ground that yields well.

CORNUCOPIA DISTRICT.

SALT.—*Silver State*, March 7: Three of Peter Rask's teams are being loaded with salt from the Desert Crystal Salt Works, for the new mill at Cornucopia. They expect to leave to-morrow, and they take about 70,000 lbs. of salt.

ELLSWORTH DISTRICT.

ORE SHIPPED.—Cor. Grantsville *Bonanza*, March 4: Since my last Frank McPherson has come to the front with a new mine discovery, and to call it a young bonanza would not be saying too much for it. It has been named after its owner, and is situated at or near Marble falls, in the Marble Falls canyon. The ledge or body of ore, as far as uncovered, will average 2 ft in width. Character of ore—horn silver, chloride and sulphurets. Mr. McPherson shipped to the Downeyville furnace last week between 2 and 3 tons of the ore, which averaged $231 per ton. The ore was not assorted, but shipped just as taken from the mine. Work in and about the Esta Bueda is progressing as usual.

EUREKA DISTRICT.

PAYMENT.—*Sentinel*, March 2: The Eureka Tunnel Co. yesterday made a payment of $9,723 to Messrs. Paul Fifield, W. J. Mulloy and M. H. Joseph, in part payment of the purchase of the El Dorado mining property. Messrs. Lyons & Keefe, owners of the Chief and Dugout mines on Prospect mountain, have extensive bodies of ore in each of the above named properties, a large portion of which will pay $200 and $300 per ton. They will commence shipping the ores to the furnaces as soon as the roads will permit.

LEWIS DISTRICT.

STARR GROVE.—*Herald*, March 1: The Clark incline is now down 300 ft and the station timbered; drift started south in 7 ft; good ore on the footwall; a level has also been started north from this station.

CHLORIDE.—Quite a stream of water flows from the face of the drift, and the ledge is looking much better than it did.

MORNING STAR.—Three shifts of men are kept going on the Morgan incline in the Morning Star mine, which will in a few days have attained a sufficient depth to connect by a level with the lower level from the Mayo incline, opening up a large block of stoping ground. Several tests have been made of the ore by milling process and good returns received. Capt. Dahlgren, managing director, has satisfied himself that he can mill the ore to a very high percentage. An assay office for this company will shortly be established in Lewis—probably in Middle Town.

EAGLE.—The contractors in the Eagle tunnel have made good headway during the past week. The flow of water is increasing as the tunnel is driven ahead. The ledge has not changed much in character.

HIGHLAND CHIEF.—The Lothwell incline in the Highland Chief mine is still being sunk and the drift south pushed ahead. Some good ore has been taken out during the week, and the indications are more encouraging.

EMMA.—The contractors on the Emma mine are still sinking the main shaft and running the tunnel.

BETTY O'NEAL.—The ore in the south lower level is still improving in quality in the Betty O'Neal, both in size and quality. The stopes are supplying the usual amount of ore, which is being piled up on the dumps, and shows for itself.

SUN BEAM.—Work on the Sun Beam is progressing and reports from the mine are flattering. The winze is still in good ore.

SPRING VALLEY DISTRICT.

PLACERS.—*Silver State*, March 7: The Chinese have resumed operations in the Spring Valley placer mines, south of Unionville. Those who left there during the very cold weather are returning, and it is not unusual to see a dozen or more of them at a time wending their way from the railroad to the mines, heavily loaded. The Chinese have taken hundreds of thousands of dollars out of those mines, every dollar of which has been shipped to China, save what they paid for pork and "blandy."

STAR DISTRICT.

HIGH GRADE.—*Silver State*, March 7: The De Soto mine at Star is said to be producing a large quantity of high grade ore. We are informed that 10 men are now at work in the mine and that the number will be increased shortly. The De Soto is the deepest shaft, and, according to all reports, one of the best mines in the county, though work was suspended on it several times before the present depth was attained. Carloads of ore shipped this winter yielded over $700 per ton in silver.

UNION DISTRICT.

ELECTION OF MINING RECORDER.—Grantsville *Bonanza*, March 4: At an election for Mining Recorder held in the town of Grantsville, County of Nye, and State of Nevada, in and for Union mining district, February 24th, 1882, the whole number of votes cast was 139. S. G. Post, having received a majority of the votes cast, was duly elected Mining Recorder of Union mining district, Nye county, Nevada, for the ensuing term.

WILLOW CREEK DISTRICT.

PLACER AND QUARTZ CLAIMS.—A note from Willow creek, on the Idaho road, to the *Silver State*, says: New placer mines have been discovered on the creek. J. F. Upson, the discoverer, has found a deposit of gravel 2 ft thick, which prospects from 5 to 25 cents to the pan, and no bedrock has yet been found. These gravel diggings are situated below the Emma mine, owned by A. H. Ruse & Sons. The Emma mine is improving as the work progresses. The tunnel is now in 130 ft, and every foot run seems to improve the appearance of the lead. There are now 50 tons of ore on the dump, which assays from $50 to several hundred dollars per ton in gold and silver. The Comstock, situated on Flat creek, and owned by Siskron & Co., is among the best mines in the district. It is prospected by a tunnel 150 ft, and there are 75 tons of ore on the dump which assays from $100 to $800 per ton. Now, all we want is mills to make our camp one among the first in the State.

ARIZONA.

GLOBE DISTRICT, *Chronicle*, March 4: A day or two since, we made a personal examination of the group of mines constituting the property of the Hoosier Mt. Co., situated about 1½ miles from Globe, in company with the obliging superintendent, Mr. W. E Spence. The first striking feature is seen in the fact that there is a mineral belt from 1,200 to 1,500 ft in width, in porphyry, syenite and limestone, lying on either side of a deep gulch, bounded on both sides by quartzite formations. We first visited a prospect shaft being worked on the Nevada, of which Mr. Spence is one-half owner, lying above and northeastward of the Hoosier. The shaft shows a well-defined ledge of copper ore, with a smooth hanging wall of syenite, the ore carrying copper glance and sulphurets, apparently very rich. This ledge can be traced for a long distance; is widening in the shaft and is undoubtedly a permanent ledge. About 900 ft below the first opening on this mine is a shaft 37 ft deep, at the bottom of which is a crosscut of 3 ft, all in solid ore, which gives an average assay of 30 per cent. copper. The width of the ledge here is not yet ascertained. On the Hoosier, more developed than either of the other mines, about 80 ft from and about 30 ft higher up than the main opening, a tunnel cuts the ledge crosswise 47 ft with 30 ft drifts, all in good ore. Below this, another tunnel runs in 32 ft, where an immense body of ore was struck and opened up to the surface, through ore all the way, except a thin capping of iron on top. This opening is over 15 ft across. From it, at right angles with the tunnel, a 75 ft tunnel is run, cutting off 4 ft of ledge matter, all good ore. Near the opening named, a winze, 110 ft deep, has been sunk, from the bottom of which a drift, in ore, runs 150 ft, where a large cave was struck, stopping work in that direction. There is on the dumps of the Hoosier, a thousand tons of pay ore, extracted during the past 6 months, and on the other mines above named about 300 tons; while there are immense bodies of rich ore in sight, estimated by a trustworthy practical miner not less than 7,000 tons in the Hoosier alone.

COLORADO.

THE GERTRUDE MINE.—Park Co. *Bulletin*, March 5: On several occasions we have been shown very rich ore from this mine. The richest we have yet seen was brought from the mine a few days since, by Mr. Bush, the superintendent. It is a very fine quality of quartz studded with free gold, and showing a large percentage of silver as well. It is taken from an 18-inch streak which was developed some weeks ago. The ore was then scattered through the rock for 3 ft. It is now condensed into a well-defined streak of 18 to 20 inches, and is very much richer. The company are working a force of 18 men, and are pushing development work only as fast as possible. They will build a 20-stamp mill early in the spring, ½ of a mile below the mine, to which they will deliver the ore by a tramway. There are between 1,500 and 2 000 tons of ore on the dumps which will mill at least $100 per ton.

CRITERION.—The ore in the Criterion is rapidly improving in quantity and quality in the tunnels, work upon which is being pushed rapidly. We are informed by a gentleman who recently visited the mine that he has visited the mines of 5 different counties in the past few months exploring mines, and he has seen nothing equal to it, all things considered, and that he looks upon it as one of the largest mines in the country.

GOLD STAR.—The Gold Star, near the Gertrude, is a very promising mine. A shaft 28 ft deep exposes a pay streak of 18 inches which carries very largely in gold, silver and copper. The various tests of the ore give a return of 30 ounces of silver, 25 per cent. copper and from 1 to 6 ounces gold. It is owned by Messrs. Traver & Co., of this place.

NOTES.—Caledonia mine on Bross, owned by the Messrs. Currie Gorman and Frazer, has recently developed some good ore. A tunnel 30 ft long, has been run on the vein 20 ft below the surface. The face of the tunnel is now in ore. A number of tons of ore taken from it milled 45 ounces silver and 35 per cent. lead. The vein is well-defined and strong, cropping for some distance on the surface. The mine joins the Dolly Varden on the east least in a desirable locality. With a 10-stamp mill going up, the Gertrude soon to build one and Blunk's mill to be put in operation, with a smelter in prospective, Montgomery will soon witness the active scenes enacted there years ago. The numerous recent rich developments at and near Montgomery are causing quite a stir in that locality. A great many prospectors are going there and locating all the vacant ground they can find.

ORE IN THE ROBINSON.—Georgetown *Courier*, March 2: The news that the Robinson mine is again in big pay will be received with pleasure throughout the entire State, and it may be the commencement of a new era to Eastern investors in Western mines. The history of Eastern companies, with but few exceptions, heretofore has been that the mines have been put on the market at too high a price and a thorough disgust for the business has been the result, and the consequence is that the stocks of many mines of merit, during the past year have been depreciated to much less than their real value. It has been a case of going from one extreme to the other. With this result the rule rather than the exception, as a matter of course nearly everybody who has touched mining stocks has suffered. But matters cannot always remain as they now are. The value of mines, like the value of wheat, will sooner or later find its true level, and when another reaction sets in the rule will be that the holders of stocks will make money instead of losing it, and if this strike in the Robinson proves to be as good as reported it may be the turning point in restoring confidence.

STRIKE AT EMPIRE.—Work was resumed a few weeks ago on the Empire City lode at Empire, by Husted, Suttle and Moore, and last week they were rewarded by opening up a vein of quartz and iron pyrite ore, 10 inches in thickness, in which are small scattered veins that carry native gold visible to the naked eye. The ore was struck in the lower adit, which has been driven at odd spells for several years, during which time it has been in cap-rock, and as the cap has now been penetrated the prospects of the mine becoming a steady producer are considered excellent.

STRIKE BY GRADERS.—Last week a promising looking lode was uncovered by the railroad graders at the Devil's Gate, carrying a vein of galena and decomposed ore from a half inch to an inch in thickness that assays all the way from 173 to 528 ounces of silver to the ton. A couple of sacks were tested this week and returned 151 ounces first-class and 74 ounces second class. The lode is evidently a large one, and the south wall is not exposed, its course being only a slight deviation from the course of the railroad grade at that place. It has been located by Messrs Vette, Burns, Ballard and Dickey, who have named it the Workman's lode.

IDAHO.

THE MINES.—Wood River *Miner*, March 1: The mines mentioned this week are situated in the Sawtooth mountain range, about 30 miles north of Ketchum, near Galena.

THE SENATE property is owned by E. P. Moore, James Wolworth and Col. E. Green. It is in Senate mountain, on which several good claims are located, and was one of the first mines discovered in the neighborhood of what is now called Galena. The ore crops out for nearly 1,500 ft and is said to be, uniformly, high grade. It is composed of sulphurets, carbonates and galena, and averages about 200 ounces in silver per ton. Last season considerable development was made, consisting of a tunnel which strikes the ledge at 100 ft from the point of entrance, and 5 shafts of various depths. All openings show ore. Over 300 tons have been taken out, assorted and partly sacked.

THE RED CLOUD.—The Red Cloud is near the summit of the main Sawtooth range, about the level of the sea. A tunnel was started in this mine a short time ago and is now in 30 ft showing good ore. An open cut has also been made, from which several tons of ore were extracted. A large amount of high grade ore is in sight and 100 tons are now piled on the dump. The Chief, which shows a very fine ledge, is 1,000 ft below, and runs parallel with the Red Cloud. Many tons of ore that will run above 100 ounces have been mined and are now upon the dump ready for sacking.

THE SENATE SMELTER.—Late last fall a water-jacket furnace with a daily capacity of 20 tons was put up at the foot of Senate mountain 1½ miles from the mine bearing the same name. Four fine buildings have just been completed for these properties consisting of the smelter building, a large boarding and lodging-house for the men, and a fine coal house in which are upwards of 10,000 bushels of charcoal ready for use in blowing in the furnace early in the spring. The fourth building is the saw mill. All the necessary fluxes, such as iron, lime, etc., are found in large deposits near at hand. The Moore Brothers, Dr. Agard and others own several good mines near the Senate group, among which are the Occident, Modoc, Last Chance No. 2, Comet and Meridian. The Last Chance No 2 has over 100 tons of ore on the dump and the others from a fourth to half the quantity. They are all easily accessible by means of wagon roads from Galena and the smelter. The owners expect to do some extensive development work as soon as mining revives with the approach of spring. There are 30 good prospects within a radius of 1½ miles of the Senate company's smelter notable among which are the President, Conway, Castle, Wellington, Leviathan and Mollie. They are all tributary to the smelter. There is ore enough in sight, within a few miles, to keep 6 furnaces of 20 tons capacity, busy winter and summer. Nearly all the mines and prospects on and near Senate mountain are to be worked, more or less during the coming season.

THE CHARLES DICKENS—FABULOUSLY RICH ORE BEING EXTRACTED.—Yankee Fork *Herald*, March 1: Last Monday we paid a visit to the famous Charles Dickens mine, where it had been reported another important "find" had been made during the past two or three weeks. After passing through 800 ft of the main tunnel, we entered the south crosscut, where a tunnel is running on the rich east vein. In the face of this tunnel, which is 900 ft in the hill and 300 ft below the surface, we found the vein to be nearly 2 ft in width, and in which we could plainly see gold and silver diffused through the ore. This vein all along the tunnel yields shipping ore that averages $2 300 per ton, the first-class average assays being $3,681.48, and the second-class $1,072.54. It will be seen by these figures that of the 45 or 50 tons of shipping ore being sacked more than half is first-class. Stoping has commenced, and by spring a large quantity of this rich ore in sight will be extracted and sacked ready for shipment. The ore in the lower ore house averages $152.63 per ton, while the upper ore house is nearly filled with richer ore than has ever been worked in the arastra. We would like to see a mill on this mine. The crushing of 20 or 25 tons of ore per day would astonish the world with the products. If the mine was in Nevada or Montana capitol would be glad to get it for $1,000,000. It is the best mine in America, and has all of the advantages of timber, mill sites, etc.

NEW MEXICO.

BULLION.—*New Southwest*: The Adams' Express Co. shipped this week, for the Mimbres M. Co., 4 silver bricks weighing 352 lbs, and valued at $5,068. Meredith & Allman received last night, and forwarded by Adams' Express, 2 silver bricks from the McGregor mine, weighing 158½ lbs, valued at $2,035. Miners are bringing a good deal of gold into Pinos Altos from the placer washings on Bear creek. The recent heavy rains have brought down an unusually heavy quantity of gold. The Bald Mountain district, 9 miles west of Silver City, is looking up. Claims have not been worked to any great extent, the deepest shaft being about 60 ft, but the ground has been carefully prospected, and the coming of spring will induce a general boom in its properties. The ores are gold and silver quartz, and assays from the top of a claim owned by Dickinson, Buck & Ross show 30 ounces in silver and $16 in gold. Other claims are equally as promising.

SHAKESPEARE.—The operations of the Shakespeare Co. M. Co. have infused new life into that camp, and mine owners, both there and at Leitendorff, are pushing work with vigor. We learn from W. J. Crosby that the furnace of the company, which was started up some three weeks since, ran for three days, reducing an average of 20 tons of ore, with a daily product of 15,000 lbs of lead bullion. The ore was from Shakespeare and Victorio, and the bullion is well up in silver. On the third day it was found that the crucible or bottom of the furnace was leaking, and work was stopped for repairs. Starting up again on the 6th inst., a two weeks' run was made on the same class of ore, the average daily output being about equal to that of the first run. It was then found necessary to shut down again, for the purpose of placing in position the new 30-ton copper furnace which had just arrived, and which is to be operated in conjunction with the silver smelter—the same power being used for both. This copper furnace was manufactured by Rankin, Brayton & Co., of San Francisco, under a patent designed by J. J. Hiertz, superintendent of the Shakespeare works. Both furnaces will be in full blast early next week. A roasting furnace and refinery are to be built immediately, and it is the intention of the company to make its works as complete as any in the country. It is the intention to buy ores on the same terms as those given at Pueblo and other points where reduction is extensively carried on. Shakespeare now has a population of about 200, there being about 75 miners at that place and Leitendorff, some 7 miles distant. A number of fine buildings are going up.

LAKE VALLEY MINES.—The work on the 20-stamp mill of the 4 companies is going forward as rapidly as possible. They have from 80 to 100 men employed on the mill work and in the mines. The machinery for the mill is partly on the ground, a portion is at Nutt station awaiting transport and the remainder is on the railroad between Deming and San Francisco. The constructor is Mr. Towne, and the mill will work 20 stamps, with a capacity to crush 60 tons of ore daily.

GROWING.—Bernalillo *News*, March 2: The steady influx of miners to the Sandias is showing itself in the corresponding increase of business in Bernalillo. New buildings are going up as if by magic, and now lines of business are being embarked in. Everything shows there is something behind our town that will shortly bring her out as a formidable rival to the self-styled "leading" towns.

MEXICO.

MACHINERY FOR SONORA.—Arizona *Citizen*, March 1: Within the past few days 2 shipments of mining machinery have been made to Sonora. The freight teams of Mr. Yjinto Aguerro were loaded and expected to leave this afternoon for Juarez with the hoisting and pumping machinery of the Caborca Mining Co., who at a depth of about 300 ft have encountered sufficient water to make the machinery in question needful. But with the incoming of the water a vein of ore has been opened, said to be about 4 ft in width and averaging from $35 to $100 per ton, of free gold bearing quartz. The company have employed about 100 men and in view of their new and improved discovery the company are pushing forward their developments, and although their 20-stamp mill is kept constantly at work, more ore is said to be on the dump than the present crushing capacity can handle. It had been a general fear among the miners of that section that the ore bodies so rich on top would not hold their own deeper down, but the strike in the Rosalia has given new life and encouragement to the many different enterprises that are on foot in that direction. The water level not only proves the mines richer than was at first anticipated, but the water itself makes good a long needed want. The mill of the Caborca Co. is about ¾ of a mile from the mine, and it is the intention of the company to pipe the water that distance for mill use, which will necessitate another trip for Mr. Aguerre to these parts, which until the present time he had not visited for the past 11 years. He says that for a long time they have lived on hope deferred but the bustling enterprise of the present time indicates that they are now soon to be realized, as the many mining companies now at work, or making preparations for work will develop the country and make it generally prosperous.

MONTANA.

DEVELOPMENTS IN LEADING MINES.—*Inter-Mountain*, Feb. 25: The Original Butte has 8 ft of high grade ore on the 200 level. The Bell is producing 40 tons of ore per diem, and the smelter is in smooth and successful operation. Operations will soon be resumed on the Acquisition. A crosscut on the 200 ft west drift of the Cora exposed 8 ft of 56 ounce ore, assaying 8 per cent. copper. The development of the Magna Charta goes bravely on with encouraging results, and the same may be said of the Alice. The battery samples in the Alice mills vary from $45 to $48, which is good enough. The Moulton is constantly improving with development, and in the 200 and 300 levels looks particularly well. The mill is doing good work, the percentage of chlorination being very high. The Belle of Butte is producing 25 tons of good ore every 24 hours. No stopes have yet been started. The owners of the Golden Rule are realizing a handsome stake from the development of that property. Louis Stettheimer has a very promising ore body in the Salvador. The Stevens is looking better than ever, and the stopes are in good shape. Joseph Ramsdell continues to ship 25 tons of ore per diem to the Montana smelter. The 120-ft west drift of the Clear Grit exposes 2 ft of $150 ore. It is now regarded as a very valuable property.

OREGON.

SUCCESS.—Jacksonville *Times*, March 2: W. Q. Brown is now engaged in thoroughly prospecting some mines in the vicinity of Canyonville for a company of California capitalists. He is meeting with flattering success and we may expect to see some extensive mining operations commenced in that district before long, for Will is full of enterprise and pluck.....Theo. Cameron, of Uniontown, informs us that all the miners in that vicinity for miles around have an abundance of water and expect to make a profitable run. The same may be said of every camp in Jackson and Josephine counties. The golden harvest will be bountiful if there is plenty of rain during the next few months.....The miners have plenty of water at last, and are happy.....The miners of Galice creek are all at work and a big yield is expected from that camp this season.....The Squaw Lake Co.'s ditches are being cleaned and repaired. Piping will be commenced soon.....Piping is now progressing in earnest at the Foreman diggings near Phoenix, which are owned by E. K. Anderson.....Gin Lin has about 20 Celestials employed in digging a ditch from Palmer creek to the red hills, several miles distant.....Miners are running on full time in Willow Springs district and increasing their forces. Extra hands are therefore in demand there.....John Marshall, of Coyote creek, has worked off a large area of ground with excellent prospects, as also have Hannum Bros. on upper Grave creek.....D. W. Anderson, Jas. Priddy and others, are now engaged in mining on Farmer's flat, with excellent prospects. They cleaned up about $150 the other day after having worked but a few hours.....Twenty-five hands are now at work on the Pacific mining company's ditch in the Wolf creek district. H. Morse and Mr. Brown, formerly of the St. Charles Hotel, at Portland, are superintending operations.....A nickel deposit is said to have been discovered in the vicinity of "Old Piney," a high and rugged mountain just north of Canyonville. A company has been organized to work it, and operations will soon be under way.

Expenditures on Mining Claims.

An Important Supreme Court Decision.

The following is the full text of a decision filed Feb. 25th, in the case of Du Prat vs. James et al., in Department Two of the Supreme Court of California. It covers several very important points to prospectors, locators, and mine owners:

This is an action to recover possession of a quartz mine. Judgment was rendered for defendants, and plaintiff appealed.

The objections to the answer cannot he eustained. The appeal is from the judgment, and the judgment roll only is inserted in the transcript. The plaintiff did not demnr to the snswer nor doss it appear that he objected to the evidence when offered to prove its allegations. The cause appears to have heen tried as if the answer was proper aud sufficient in all respects. Such objections as those of plaintiff, will not he permitted to he raised for the first time in this Court. (Racouillat vs. Rene, 32 Cal., 450; Cave vs. Crafts, 53 Id., 135.)

The cases of Atherton vs. Fowler, 6 Otto, 513, and Fletcher vs. Mower, 6 Pac. L. J., 521, cited hy plaintiff's counsel, have no application to this case.

It is contended that plaintiff was lawfully in possession when defendants made their location of the mine in question, and that defendants had no right to locate when their locations were made. It appears from the findings of fact, that the parties under whom plaintiff claims, properly located the mining claim or claims in question prior to tho 10th day of May, 1872, that the defendants entered upon and located the claims or mine partly on the first day of January, 1881, and partly on the fifth day of January, 1881, and that they filed for record with the proper Mining Recorder, the notices of these locations, as required hy the rules and regulations of miners, within 30 days from the date of such notices. It further appears from the findings, that the defendants made such locations on the ground thst plaintiff had failed to perform the lahor required hy the Act of Congress of May 10, 1872, and the acts amendatory thereof.

By the fifth section of the Act of Congress of May 10, 1872, it was provided as follows:

"On each clsim located after the passage of this Act, and until a patent shall have issued therefor, not less than $100 worth of lahor shall he performed or improvements made during each year. On all claims located prior to the passage of this Act, $10 worth of labor shall be performed or improvements made *each year* for each 100 ft. in length along the vein until a patent shall have heen issued therefor; hut when such claims are held iu oommon, such expenditure may he made upon any one claim; and upon a failure to comply with these conditions, the claim or mine upon which said failure occurred, shall he open to re-location in the same manner as if no location of the same had ever been made." (17 U. S. Stats. at Large, 92).

On the first day of March, 1873, Congress passed an Act hy which the provisions of the 5th section of the Act of May 10, 1872, which requires expenditures of lahor and improvements on claims located prior to the passage of said Act, were so amended "that the time *for the first annual expenditure*" on such claims was "extended to the tenth day of June, 1874." (17 U. S. Stats. at Large, 483; Sec. 2,324, U. S. Rsv. Stats.)

By Section 2,324 of the Revised Statutes of the United States it was thus provided:

"On all claims located prior to the tenth day of May, 1872, $10 worth of lahor shall he performed or improvements made by the 10th day of June, 1874, and each year *thereafter*, for each 100 ft. in length along the vein until a patent has heen issued therefor; hut where such claims are held in common, snch expenditure may he made upon any one claim; and upon a failure to comply with these conditions, the claim or mine upon whioh such failure occurred shall he open to re-location in the ssme manner as if no locstion of the same had ever heen made; *provided*, that the original locators, their heirs, assigns, or legal representatives, have not resumed work upon the clsim after failure and before such location."

It will he observed that hy this section it was provided that the labor to be performed or improvements to he made on olaims located prior to the 10th day of May, 1872, were to he performed or made hy the 10th day of June, 1874, *and each year thereafter*, until a patent had heen issued for such claim. The words "*and each year thereafter*," were here first added to the date mentioned, viz: 10th day of June, 1874.

The Revised Statutes of the United States were approved hy Act of Congress, passed on the 22d of June, 1874. Section 5,595 of this revision, consisting of 73 titles, declares that these titles embrace the Statutes of the United States, general and permaaent in their nature, in force on the 1st day of December, 1873. The acts above referred to, passed prior to the date last named, were repealed hy force of section 5,596 of the revision, hut all rights accruing or accrued under the Acts repealed were preserved by the provisions of section 5,597.

Congress further amended this 5th section of the Act of 1872, hy an Act passed on the 6th day of June, 1874. By this amendment, the time for such "*first annual expenditure*," on claims located prior to the Act of 1872, was extended "to the 1st day of January, 1875." (18 U. S. Stats. at Large, Part 3-61.)

The foregoiug Act of the 6th of June, 1874, is not affected hy the Revised Statutes, hut has as full effect as if passed after the enactment of the revision, *i. e.*, aftsr the 22d of June, 1874, and so far as it varies from or conflicts with any provision contained in the revision, hss effect es a suhsequent statute, and repeals any portion of the revision inconsistent with such statute. This results from the provisions of section 5,601 of the revision.

By the Act of the 22d of January, 1880, Congress amsnded section 2,324 of the Revised Statutes, hy adding thereto the following words: "Provided, that the period within which the work required to he done annually on all unpatented mineral claims shall commence on the first day of January succeeding the date of the location of such claim, and this section shall apply to all claims located since the 10th day of May, A. D. 1872." (See 21st U. S. Stats. at Large, 61.)

The counsel for appellant puts forth a contention in relation to the Act of June 6, 1874, in these words:

"The act of June 6, 1874, only amended the act of May 10, 1872, in extending the time for doing the annual work, which the existing laws required to he done hy June 10, 1874, to Jan. 1, 1875, hut did not make any arhitrary rule affecting the date of locations msde prior to May 10, 1872, so that that act became *functus officio* on the expiration of the 1st of Jan., 1875."

If hy this it is intended to say that the act of June 6, 1874, had its full effect on the 1st day of Jan., 1875, and that no provision of law then existed in regard to the work of improvements on a mining claim requiring that they should he performed or made in each year succeeding Jan. 1, 1875, we think the learned counsel has fallen into an error, as an examination of the various acts ahove referred to will show. What is said herein on this point, relatee only to claims located prior to the 10th of May, 1872, such being the character of the claims involved in this case.

By the act of May 10, 1872 (see Sec. 5), the lahor or improvements required as to such claim were to he performed or made "*each year*." The first amendment to this act was made on the 1st of March, 1873, and by it the time for "the first annual expenditure" was extended to the 10th day of June, 1874. The legislation on this matter next succeeding, according to the provisions of Sec. 5,601 of the revised statutes was Sec. 2,324 of the revision (see quotstion from it ahove), which required the lahor or improvements to he performed or made hy the 10th of June, 1874, "*and each year thereafter*." Then came, not in order of time, but as it went into operation, the act of June 6, 1874, hy which the time for the "*first annual expenditure*" for lahor or improvemsnts, was extended to the 1st of Jan., 1875.

But, as we have seen, this act has effect so far as it varies from or conflicts with any provision contained in section 2,324 of the revision as a suhsequent statute, and repeals any portion of the revision inconsistent with it.

The only inconsistency or conflict with the revision, Sec. 2,324, is as to the date to which the first annual expenditnre is extended, which, by Sec. 2,324, is to the 10th day of June, 1874, and hy the act of June 6, 1874, to the 1st day of January, 1875. There is no conflict or inconsistency so far as regards the words "*and each year thereafter*" in the Sec. 2,324, and they remain. The requirement, then, as enacted hy the legislation of Congress, was, after the 22d of June, 1874, that the first annual expenditure must he made hy the first day of January, 1875, and each year thereafter. (See Weeks on Mineral Lands, Sec. 69.) This, in our view, is the correct interpretation of the acts of Congress relating to the point under discussion.

If the act of the 22d of January, 1880, applies to the case in hand, of which we entertain some donht, the meaning is the same.

The learned counsel for appellant seems to lahor under the impression that the section 2,324 took effect suhsequently to the act of June 6, 1874; hut this is a misconception, as will he seen hy examining section 5,601 of the revised statutes, ahove referred to.

Upon a failure to comply with the conditions mentioned in section 2,324, among which are those which relate to lahor and improvements ahove stated, hy the provisions of the eame section, the claim or mine is "open to re-location in the same manner as if no location of the same had ever heen made."

The Court found that plaintiff failed to perform the lahor or make the improvements thereon as required hy law during the year 1880, commencing on the first day of January, 1880, and ending on the 31st of Decemher of the same year; that it wae open to re-location on the 1st and 5th days of January, 1881, on which days defendants made their locations.

It is argued hy oounsel for appellant, that the location on the 1st of January, 1881, was premature; that he had all that day to perform the labor or make the improvements required hy law.

The question is not free from difficulty. The act of 6th of June, 1874, extends the time *to* the 1st day of January, 1875. In Bradley vs. Rice, 13 Maine, 201, in the construction of a conveyance of land, which described a tract of land as running "*to Flying Pond*," the question was whether the tract ran into the pond or was hounded hy the water of the pond; the Court said: "To, from and hy are terms of exclusion, unless hy neceesary implication, they are manifestly used in a different sense." The tract of land was held to extend to the pond, sxolnding any portion of it.

In considering a question of the same character arising upon a deed in Bonney vs. Morrill, 52 Maine, 253, the same Court said: "From" an object or "to" an object "excludes the terminus referred to." The call on which the construction was made described a course as easterly "to land now or formerly owned hy Isaac Bonney," etc. The land of Bonney was held to he excluded.

If the question under consideration is to be determined upon the words of the act of the 6th of June, 1874, the 1st day of January, 1881, mnst he excluded from the time within which the plaintiff had to perform the lahor or make the improvements required for the year 1880. But it may be contended that the effeot of section 5,601 of the Revised Statntes is merely to substitute the 1st day of January, 1875, for the 10th day of June, 1874, in section 2,324, and that the section ought to he read, making snch suhstitution, thus: "Lsbor shall he performed, or improvements made *by* the 1st day of January, 1875."

If "hy" is a word of exclusion, as held in the above-cited case from 13 Maine, then the same conclusion must he reached as above, as to the 1st day of January, 1881, viz.: that it must he excluded from the period during which the lahor had to he performed, or the improvements made, for the year 1880.

In Rankin vs. Woodworth, 3 Penross and Watts, 46, it was held that a contract to complete work *by* a certain time, means that it shall be done hefore that time. The contract was dated in February, 1815, and was "to huild a sawmill" and "to have it completed hy Novemhsr next." The Court thus expressed itself in regard to it: "By the contract the work was to hs finished *by* the ensuing month of Novemhsr, which in the popular acceptstion of the word excludes the month. When a thing is ordered hy a particular day, it is with a view of having the use of it on that day. Thus a coat is ordered hy Sunday, with a view of wearing it to chnrch. And the popular agrees with the philological import of the word, which is explained hy our great lexicographer, by the words 'near, heside, passing, in presence;' all of which denote exclusion."

The proper interpretation of the legislation of Congress on the subject is, in our judgment, that *by* is used as a word of exclusion, and therefore that the plaintiff was not entitled to perform the lahor or make the improvements for the year 1880, on the first day of Jannary, 1881. A review of the acts of Congrese in regard to this point, leads us to the conclusion that it was the intention of Congress to confine the period, after the first day of Jan., 1875, in which the labor or improvements were to be performed or made by the clsimant of a mining claim, to the calendar year, commencing on and including the 1st day of Jan. of the year, and ending with and including the last day—the 31st of Decemher. This seems to he the construction put on this legislation by the officers of the Department of the Interior. (Sse Sickel's Mining Laws and Decisions, 373, 392, 393, 394.)

The Court finds that the plaintiff performed the requisite amount of lahor on the mine during the years preceding 1880. The finding as to the year 1880 is, that plaintiff "cansed three days *work* to he performed in and upon said claim," hut does not find the valne of the *work* performed. We cannot see that the work did not amount to $150 in value. It is not found whether this *work* consisted of lahor performed or improvements made on the claim. *Non constat*, hut it may have heen improvements made on the claim worth $150. This Court cannot know judicially whether this work consisted of lahor or improvements, or what the worth of it was. For the failure to find as to this worth or value which was in issne, the jndgment mnst hs reversed and the canse remanded that the worth or value of the work may be fonnd hy the Conrt below. In this course, we pursne the practice adopted in Billings vs. Everett, 52, Cal., 661.

Judgment reversed and canse remanded to the Conrt helow, with sn order to the Court to find on the said issue on the evidence taken or on such other evidence as may he adduced as to said issne, and thereupon to proceed to render judgment in accordance with the views expressed in this opinion. So ordered.

The North End.

The *Enterprise* says: Matters are looking quite hright at the north end at present. There was last evening but a small partition of solid ground hetween the drift going north on the 2700 level from the joint Mexican-Union winze and that south from the Union-Sierra Nevada winze. A set of holes was heing put in last evening which it was calculated would knock a hole through on heing fired. As soon as a track ie laid through the drift, work will he resumed in the ore recently found in the Mexican—not waiting to dig a drain, as that can be done at leisure.

The winze started on the 2500 level of the Union, to the eastward of the ore hody, was yesterday down 18 ft. and was already in good milling ore. As it was not expected that ore would he reached until the winzs had attained a depth of 25 or 30 ft., it would seem that the deposit is widening with depth. The ore is found to he richer than on the 2500 level. It is good milling ore, and ie being saved for redncton. A train of ore cars was sent out to the works yesterday, which looks somewhat like business. The ore taken out will at once be sent to mills for reduction.

There is much interesting ground that can now soon be opened in this section of the lode, and the chances are that some good developments will he made. The water in the winze down from the 2500 to the 2600 levsl is now, for some cause, receding at the rate of 2 ft. per day. This is what is known as the "wet winze." It will he remembered that some nine drill holes were run in various directions from its bottom, some of which penetrated ground yielding good assays. At the rate at which the water is now draining out of this winze, they will soon he able to drift from its bottom and prospect the surrounding country.

The Flooded Mines.

The Water in the South End Mines—Its Probable Source.

Three theories have heen advanced regarding the water lately struck in the Exchequer mine, which has flooded in so short a time all the mines south of the Bullion, except the Alta. Their discussion being a matter of great importance to the future of the south end mines, an *Enterprise* reporter has gathered the following facts from the leading mining men here:

The first theory advanced was that the water pumped hy the Bullion folks into the Julia had found its way into the Exchequer mine and had flooded the south end. The fallacy of this hypothesis can he easily demonstrated. The Exchequer drift on the 2800 level is 600 ft. east of the Bullion shaft, and its face 400 ft. south. Ahout eighteen months ago, hefore the Yellow Jacket pump hroke down, the Exchequer folks ran a diamond drill hole west 60 ft., and struck 20 miners' inches of water. At that time the Bullion mine was heing worked on the 2450 level, and its water did not diminish on account of water having heen struck in the Exchequer, nor did the water increase after the Yellow Jacket pumps hroke down, and the water in the mines to the south rose 200 ft. above the lower Bullion level. When the Bullion mine closed down the water rose to the 1950 level in the new shaft, and remained at this level, when the Jacket was drained to the 3000 level. When the Bullion mine started to pump its water in the Julia 1800 level, no excess was felt in the Jacket water. Therefore, no connection could exist hstween the water of these mines. Furthermore, since the Bullion started to pump its water in the Julia 1800 level ahout six inches daily have been pumped from the Bullion, or 180 miners' inches per month, which, during the four months the mine has heen running, makes a total of 730 miners' inches. After the watsr was struck in the Exchequer, for the first five days the Jacket pumped up and hailed a total of 510 inches. From the 17th to the 23d of the month, inclusive, the Jacket pumped 70 miners' inches daily, making a total for six days of 420 miners' inches. Therefore, since the water was struck on the 12th of the month, the Jacket mine has pumped and hailed a grand total of 930 miners' inches, being 200 minere' inches in excess of the total water pumped hy the Bullion company from the day they started up to the present time. So that, had the Exchequer mine drained all the water pumped hy the Bullion company into the Julia, the Jacket mine sbould bs dry to-day to the 3000 level, instead of the water having gained at the ratio of 100 miners' inches per 24 hours on the pumps. Many persons will still claim that this water goes somewhere snd will find an ontlet somewhere. If they will, however, remember the great absorhing power of rocks, clays and dscomposed quartz, and if they will figure the area for absorption and the amount to he ahsorbed, they may find the solution of a problem which they cannot to-day understand.

The second theory is that the water comes from the west wall. Surveys, however, show this supposition to he false, as the drift in Exchequer is at least 200 ft. east of the west wall and the distance from the west wall to the water channel has heen demonstrated to he 200 ft. farther, so that the Exchequer drift must he at least 400 ft. east of any west wall water.

The third theory advanced as to the sonrce of the water is that it comes from an extensive hody of quartz lying in the east country. The correctness of this can hardly he disputed when it is remembered that four years ago, on the 2400 level of the Exchequer, near the Alpha line, the drift rnn on the east side of the vein strnck a stream of water of ahout 10 miners' inches. The drift was immediately stopped and hulkheaded and a drift was started to the west, which drift was extended through the Exchequer mine without encountering any water, and in this drift and to the west of the water were encountered the streake of ore which have led so many people to believe in the existence of ore in the Exchequer mine. It seems now very prohahle that the Exchequer drift on the 2800 level has encountered the same water discovered four years ago to the east of the ore-hearing quartz, and that thie water is in itself an almost certain indication of ore-bearing quartz lying to the west of it. Add to this the indications of the diamond drill run 18 monthe ago on this level, and the pieces of quartz washed out hy the water, which yielded low assays, and it hecomes a certainty that the water on the Exchequer 2800 level comes from an immense qnartz hody, prohably extending several hundred feet ahove the 2800 level, and which, when drained, will in every prohability reveal an ore body.—*Enterprise.*

THE Girard mill of 20 stamps was started at Tombstone on the 16th.

Treating Low Grade Ore.

The *Register-Call* (Central City, Col.) thus describes the new concentration works of the Rara Avis Co., in Eureka Gulch:

The ore is trammed in cars from the adit workings to the mill building (situate at the mouth of the adit), and dumped into an ore house, which forms an L to the mill building. The ore is then put through a Champion crusher—an improvement over the Blake pattern—and thence it passes by an automatic bucket feeder to a Thompson pulverizer, 40 inches in diameter, which has two cylindrical side issues 40 inches in diameter, the screen issues being of 40 mesh, through which all ore treated by the pulverizer discharges. The principle of the pulverizer is centrifugal force brought to bear within a certain circumference by means of the ore coming in contact with three cast iron balls weighing 200 lbs., the ball pulverizing the ore fed into the pulverizer to a degree of fineness to admit of its discharge through a 40 mesh screen, or finer, if deemed necessary. Below the pulverizer is placed a table, which is to be covered by amalgamated copper plates, and over which the ore runs through the pulverizer passes. This is for the purpose of amalgamating the free gold contained in the matter undergoing treatment. From the amalgamated table the ore passes through troughs to a tank and elevator to an upper tank, from whence it passes to concentrators, one of them being what is known as an Embry, which is nothing more nor less than an endless belt operated by jig motion, being applied by eccentrics. Alongside of the Embry are four of Bradford's concussion tables covered with rubber and so arranged as to separate the slimes or gangue from the mineral. The discharge at the foot of the tables works automatically by a simple contrivance, that of a sliding division gate—it might be termed—the slimes or refuse passing off to one side and the clear mineral to the other. Should the slimes contain values to a certain percentage, they are returned and submitted to further treatment.

The mill has a capacity of from 40 to 50 tons of crude ore per day. The motive power is that of a 70-horse power boiler and a 70-horse power Wells patent balance engine. At present the company are utilizing 25-horse power, which is amply sufficient to speed the mill to a proper capacity. A spring of living water inside the mill building affords an ample amount of water for steam purposes. The water used in the Thompson pulverizer and on the tables is collected from the drainage of the level and gulch and deposited in large sized tanks. Those best acquainted with the details of the mill workings claim that two miners' inches of water is all that is required to successfully treat ores. It will require several days yet before the success of the works can be fairly demonstrated.

Men in the Montana Mines.

The Helena *Independent* says: The quartz mines surrounding Helena now furnish employment to nearly 2,000 men, and as yet not one-tenth of the discovered mines are being worked beyond what is necessary for representing each year. We give below a list of some of the principal mines, but this list is necessarily incomplete, for although there are many other mines that are now being worked, we are not advised as to the number of men employed in each:

Alta Montana	180
Gregory	135
Gloster	130
Belmont	70
Legal Tender	51
Drum Lummon	30
Empire	25
Bonanza Chief	18
Lee Mountain	15
Hickey	14
Bald Butte	14
Poor Man	12
Union Lode	10
Stemple	10
Little Jennie	12
Iron Age	5

In addition to the above there are a number of mines working from three to ten men, and perhaps 200 others that are being slowly developed by the owners with the assistance of one or two hands. It will be safe to estimate that these altogether furnish employment to as many more men as contained in the list above given.

In addition to the miners there are probably 400 men engaged in ore-hauling, chopping wood, burning charcoal, and procuring fluxing material, which would run the list of men which the quartz interests surrounding Helena actually employ, up to about 2,000. This force, if working in one camp, would be sufficient for the nucleus for a city of 10,000 inhabitants. As it is, Helena of course derives the benefit. The sum of money paid to these men monthly amounts in round figures to $200,000. It is safe to say that this sum will within three years or less be increased ten-fold.

THE January product of the Tombstone district, Arizona, is reported at $375,000, of which $121,800 is credited to the Contention Con., $110,000 to the Tombstone, and $100,000 to the Grand Central. The Tombstone *Nugget* of Feb. 4th says that the Grand Central has paid $650,000 inside of a year.

THERE are now seven mills in operation in the Bodie district.

Useful Information.

Painting of Cement and Plaster.

Much difference of opinion prevails respecting the question of painting Portland cement, and we have seen work painted a few weeks after the cement had set, which has stood well. There is one point which has a great deal to do with the question of successful painting, namely, the absorbency and dryness of the brickwork itself. Many new walls saturated with moisture are cemented, and in this condition no paint can possibly stand, if laid on too soon. It is a good and safe rule to enforce, that Portland cement work should not be painted within a year of its completion, to allow it to dry thoroughly; but we are safe in saying the majority of new fronts are painted before they have been finished three months. A very desirable precaution seems to be to coat the work with linseed oil first.

The painting of plaster work requires the same care, and the lime works out in small bubbles, destroying the paint. In painting plaster, white lead and linseed oil, with a little drier, is recommended by one authority. This coat should be of the consistence of thin cream, so that the oil is absorbed into the plaster in a few hours. In a day or two another thicker coat may be applied, and a third a few days after rather thicker, followed by the finishing coat. Four coats are not too much for good work. By the absorption of the oil into the plaster, the surface becomes hardened, and may be washed. Another method to facilitate this absorption is followed by painters, which is to give the plaster two or three coats of boiling linseed oil, and then to apply the other coats of paint. We are inclined to think the application of the oil before the paint a better plan, to insure a thorough saturation of the material. The color of Portland cement, and the uneven tints it sometimes assumes, is the main reason why painting is resorted to. For this reason, we think it may be worth the attention of manufacturers to turn their consideration to the subject, and those using cement as a stucco, might also prevent a blotchy and uneven tint by attending to the preparation of the wall and the sand they use with the cement—*Wood and Iron.*

TO CLEAN INCRUSTED SUPPLY PIPES.—A correspondent of an exchange writes: "One of the most annoying accidents that can happen to the steam engine runner, is to have his water supply pipes choked up with lime and other solid incrustations. Especially in the hot water pipe lime is apt to settle and incrust on the iron pipes, till they become completely filled up, so that no water whatever can pass to the pump or injector which forces it into the boiler. In such cases it is customary to take up the pipes and try to loosen the solid matter by pounding on the pipe and breaking it out, or by making a fire along its whole length and burning it out. In a very recent obstinate case one end was stopped up with a plug, and, standing it upon end, coal oil was poured in as long as any would go in, and the whole was left to stand till morning, when the whole was slid out in a solid core. While this may not always work, it is certainly worth trial in obstinate cases."

HOW TO MAKE BROWN BRASS.—The following recipe is said to produce a good brown tone upon brass: The article, having been thoroughly cleansed and freed of all traces of grease, then polished, is dipped for about half a minute into a cold solution of 10 grains of hypomanganate of potash, 50 grains green vitriol, 5 grains muriatic acid, and 1 liter water; then rinse well and dry in soft sawdust; if a reddish cast is desired, dip the article into a second bath heated to 60° C., of 10 grains chromic acid, 10 grains chloric acid, 10 grains hypomanganate of potash, and 50 grains blue vitriol (sulphate of copper) dissolved in 1 liter water. The latter mixture alone produces a light bronze. The article may afterward be heated in an oven, which operation, it is said, produces a very rich tone.

GUT BELTING is made chiefly of sheep's entrails. They are on an average over 50 ft. long, and after being cleaned, are put into brine, when they shrink in thickness very much. They are then treated as if they were twine to make a round rope from, or they are connected in strands and woven on a loom into flat belts in the same way as ribbon is made. They are now made in Oakland, Cal., round ones, from one-sixteenth to one and one-half inches in diameter, and the flat ones of any size desired. They are so strong that a three-quarter-inch round belt will stand a strain of over seven tons, and a three-eighth-inch, consisting of 150 strands, almost half as much. They are claimed to last 10 years, while the best hemp rope, with the usual usage, scarcely lasts three years.

CORNSTALKS AS FUEL.—An Iowa farmer who has both wood and coal on his farm burns cornstalks for fuel to warm his house, and claims that they make the best and cheapest fuel he can get. He uses a large stove, and burns the stalks in tightly-bound bundles, weighing about 40 lbs. each. A bundle burns three hours (without flame) in an air-tight stove. The large stove offers so much radiating surface that it does not need to be very hot. Five bundles a day, or 600 for the winter, suffice to keep the stove going and the house warm.

SOME curious reactions of milk have been noted by M. C. Arnold: If a little tincture of guiacum be added to fresh milk a blue color is produced; but milk heated to 80° or more remains unchanged. Sour milk assumes the same tint, unless the reaction is checked by the use of mineral acids and alkalies. When a little paste starch mixed with iodide of potassium is introduced into milk to which old oil of turpentine had been previously added, a fine blue hand appears at the surface of contact and spreads rapidly. Milk freed from albuminous matter does not give this reaction. If to fresh milk there is first added acetic acid to precipitate the caseine, then some caustic potassa, and lastly a trace of a solution of sulphate of copper, the violet reaction characteristic of peptone does not appear, but if the milk is allowed to stand 15 to 20 hours before this treatment, the violet color is obtained. The blue color, the author thinks, is the result of ozone.

WHAT MAKES CORN POP?—Chemists who have examined Indian corn, find that it contains all the way from 6 to 11 parts in a hundred (by weight) of fat. By proper means this fat can be separated from the grain, and it is then a thick pale oil. When oils are heated sufficiently in closed vessels, so that the air cannot get to them, they are turned into gas, which occupies many times the bulk the oil did. When popcorn is gradually heated and made so hot that the oil inside of the kernels turns to gas, this gas can not escape through the hull of the kernels, but when the interior pressure gets strong enough, it bursts the grain, and the explosion is so violent that it shatters it in the most curious manner. The starch in the grain becomes cooked and takes up a great deal more space than it did before.—*Agriculturist.*

TO DETECT LEAD IN TIN VESSELS.—For tinning kitchen utensils a very impure tin is used, containing lead in more or less quantity. Considering the dangerous nature of this sophistication, it will be well to have a ready means at hand to determine if the tinning of a vessel contains lead. For this purpose a small bit of tin is detached and put into a watch glass, with a drop of nitric acid and two or three drops of water; the glass is then gently heated over a flame, and when the solution is complete a few drops of water and a concentrated solution of iodide of potassium are added, when, if lead is present, a yellow precipitate will be the result.

GAS-FITTERS have recently made a most useful application of photography. They photograph the gas flames given by different burners or jets, so that a customer can see if the shape and form of a light will suit him before he gives his order. As the flames are moreover depicted "life-size," the purchaser can always tell whether his jet is up to the standard.

Good Health.

RAPID BREATHING AS AN ANÆSTHETIC.—Dr. M. T. Yates, in a letter published in the *Bibli cal Recorder*, says of the surgical operation to which he has recently submitted: "My doctors said that they had seen it stated by an American doctor that if a person would breathe as rapidly as possible under an operation, he would not feel the pain of cutting, and they wished to try it on me, to which proposition I assented. Dr. MacLeod superintended the breathing—which was like that of a dog on a hot summer day—holding, out of my sight, a handkerchief in his hand, to be dropped as a signal when he saw the color come to my face, for Henderson, the operating doctor, to go ahead. When MacLeod told me, 'That will do,' I was surprised to find that the operation had been performed. This I have tried three times, and have not at either time felt more pain than is usually inflicted in the case of vaccination. I heard the knife rip through the flesh like the sound produced in cutting leather, but did not feel the pain. What is the philosophy of this kind of an anæsthetic? Is it simply a diversion of the mind?—*Richmond Herald.*

COLD FEET.—The association between cold feet and sleeplessness is much closer than is commonly imagined. Persons with cold feet rarely sleep well, especially women; yet the number of persons troubled is very considerable. This is the plan to adopt with cold feet: They should be dipped in cold water for a brief period. Often just to immerse them and no more is sufficient; and then they should be rubbed with a pair of hair flesh-gloves, or a rough Turkish towel, till they glow, immediately after getting into bed. After this a hot-water bottle will be successful in maintaining the temperature of the feet, though without this preliminary it is impotent to attempt to do so. Disagreeable as the plan at first may appear, it is efficient, and those who have once tried it continue it, and find that they have put an end to bad nights and cold feet. Pills, potations, "night-caps," and all narcotics fail to enable the sufferer to woo sleep successfully. Get rid of the cold feet and the sleep will come of itself.

ROAST PORK is the hardest food to digest known to the domestic table. It requires over five hours for the process after being taken into the stomach. Boiled rice will digest in one hour, roast or boiled mutton in three hours, turkey in two hours, beef, fried, four hours, roast or broiled, two and a half hours.

HAD HIS HEARING RESTORED.—A rather singular occurrence recently happened near the Western and Atlantic crossing on Alabama street, says the Chattanooga (Tenn.) *Times*. Mr. F. Matthews, track master of the Alabama and Great Southern road, has been totally deaf in his left ear for a number of years, caused by cutting railroad iron in a repair shop, and has consulted a number of prominent physicians and auriculists without deriving any benefit from them. A switch engine was standing near, as Mr. Matthews was crossing the track, and, starting up at that moment, the wheels suddenly slipped on the rails, while a heavy jar ensued, followed by a sharp rush of escaping steam. As soon as the noise had in a measure subsided, Mr. Matthews remarked to a friend standing near that his ear had cracked, and began to pull out fragments of some substance which seemed as hard as rock. Upon further investigation he found that his hearing had been entirely restored, and that what experienced men had failed to do had been accomplished by one of the most natural and ordinary occurrences of every day life.

THE SUNNY SIDE OF DEATH.—Take the sunny side of death. Sooner or later it must come to all, and at the latest it is only a few swiftly-passing days distant. Kings and potentates have no refuge from the summons of the dread messenger. Death is the great leveler of man, and dust to dust is the heritage of all. Why, then, should we shrink from its contemplation? Why banish it from our thoughts with a shudder? It is not rational to permit death to shadow our lives; nor is it rational to turn in terror from what must as surely come as to-morrow's sun. Those who are suddenly chilled day after day by the thoughts of death, either shadow their lives by misdeeds or reject the philosophy that should make every well-ordered life wait serenely for its end. The rational apprehension of the upright man is, not that he may fall too soon in the race, but that he may linger too long and outlive everything but hope.

SUGAR MEAL.—A new danger has appeared in feeding "sugar meal," which is sold by the glucose factories for fodder. This meal is supposed to be the non-starchy part of corn, and to have come in contact with nothing but water in the course of its preparation. If this were true there ought to be no harm in feeding it when fresh. The fact is, that in the vicinity of Buffalo, N. Y., it has gained the reputation of sour meal, from its strong acid taste. An unusual amount of cholera infantum has lately prevailed in a city in the western part of New York State, which is claimed to be due to the acid in the milk of the cows fed on this meal. Cheese-makers have had such bad luck in making cheese, which they claim, also, is due to the acid in the meal, that they have, in many instances, refused to receive milk from dairies where this milk is fed.

AILMENTS PRODUCED BY TURPENTINE FUMES. The effects of turpentine on some 300 painters having been studied by a French physican, he now publishes the conclusions, namely, that these effects can never be so severe as to cause death, unless they be volatilized in an extremely confined space—also, that where there are free movement and good ventilation, no liability to fatal accidents exists. The vapors of turpentine coming from different sources, it appears, have not all the same energy, that of the French product, for instance, being far less injurious than the Hungarian or American. The most general form of indisposition exhibited—usually among new workmen, and directly attributable to the turpentine—are headache, watering of the eyes, coryza, cough granulations on the larynx, and disordered digestion.

WHAT TO DO FOR A SICK-HEADACHE.—Don't take a cup of strong tea, nor a dose of "blue mass," or a lot of anti-billious pills, but drink a pint of warm (not hot) water. Keep on drinking until vomiting is induced. That is the better way to relieve the stomach of its undigested, decomposing mass of food. If anything more is needed, take a hot enema, apply hot fermentations to the bowels, and drink freely of hot (not merely warm) water. Eat little or nothing for 24 hours, then commence with fruit or some simple diet, avoiding meats, butter, pastry, and all other indigestible food.

DIED FROM HAVING HER EARS PIERCED.—A Brooklyn girl, of 18, died the other day from the effects of having her ears pierced. A few days before Christmas she was told that she was going to have a pair of earrings for a present, and in order that she might wear them on the holiday, she immediately had her ears pierced by her brother-in-law. Unfortunately she caught cold, and three days later erysipelas set in, which was followed by meningitis, and after lingering about a week she died.

MINING PRIMER.—Oh, gimmineddi! What is this? This is a hoisting works. What is it for? It is used to hoist the price of stock. But sometimes the price is so heavy that you could not hoist it with a ton of nitro-glycerine. Do they ever use hoisting works for any other purpose? Oh, yes; sometimes they use them to hoist ore into the mine before an expert comes to examine it. Then the expert makes mistakes. What does he do then? Oh, he blames it on the general manager. Do editors ever have hoisting works? We should extemporize. What for? To hoist in liquid philosophy.—*Esmeralda Herald.*

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Hydraulic Gravel Elevator; Exhibition of Fossils; An Important Mining Decision, 153. The Week; Talk Up Your Camp; On the Occurrence of Vivianite in Los Angeles County; Academy of Sciences; Ore Concentration, 160. On Minerals; How Plants Grow, 161. Notices of Recent Patents; The Debris, 164.

ILLUSTRATIONS.—Method of Working Shallow Gravel Claims with Hydraulic Gravel Elevator, 153. Section of Tree Magnified to show Cellular Growth, 161.

CORRESPONDENCE.—Southern Arizona, 154.

MECHANICAL PROGRESS.—Belting Leather; Practice vs. Theory; A New Use for Spence's Metal; Close-Fitting Fire-Doors; A New Style Steam Press for Forming Axes; Slide Valve and Link Motions, 155.

SCIENTIFIC PROGRESS.—Power of the Microscope; What is Materialism? Magnetic Bricks; Animal Combustion; Eleven Score Asteroids; Comet Seeking; A "Telelogue," 155.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Assessments, Meetings and Dividends, 156.

MINING SUMMARY from the various counties of California, Nevada, Arizona, Colorado, Idaho, New Mexico, Oregon, Utah, Montana and Mexico, 156-7.

USEFUL INFORMATION.—Painting of Cement and Plaster; To Clean Incrusted Supply Pipes; How to Make Brown Brass; Out Belting; Cornstalks as Fuel; Curious Reactions of Milk; What Makes Corn Pop? To Detect Lead in Tin Vessels, 159.

GOOD HEALTH.—Rapid Breathing as an Anæsthetic; Cold Feet; Had his Hearing Restored; The Sunny Side of Death; Sugar Meat; Ailments Produced by Turpentine Fumes; What to do for a Sick Headache; Died from Having Her Ears Pierced, 159.

MISCELLANEOUS.—A New Dry Ore Concentrator; Miners' Lamps, 154. Expenditures on Mining Claims; The North End; The Flooded Mines, 158. Treating Low Grade Ore; Men in the Montana Mines, 159.

Passing Events.

During the past and previous week the final arguments in the now famous Gold Run hydraulic mine suit have been presented to the court. Space prevents our presenting entire the exhaustive arguments of the learned counsel on both sides, though we give, in another column, an abstract of some of the speeches. Within a few days now this most momentous question will be decided by Judge Temple, although, no doubt, it will have yet to go before the Supreme Court of the United States for final adjudication, no matter which one wins.

The weather this week has been disappointing. Up to hour of writing (Thursday afternoon) no rain has fallen, though the indications are favorable.

Meetings were held in this city and all over the State, as well as in Oregon and Nevada, last Saturday, to express the wishes of the people in favor of restricting Chinese immigration. These were well attended by enthusiastic crowds. The bill on this subject before Congress has passed the Senate.

THE Richmond Consolidated Mining Co. has just paid a quarterly dividend of $2.50 per share at London, aggregating $135,000, and making a total to date of $3,637,600, equal to $67.87½ per share. The mine adjoins the Eureka Consolidated, which has not paid a dividend since last year, and which only produced $60,000 in January.

THE Leeds mine is again producing bullion, but it owed $13,115 on the 1st.

Talk up Your Camp.

It has generally happened that the most successful mining camps have been the best advertised camps, as, for instance, Leadville, Deadwood, Tombstone, Bodie, Wood River, Butte, etc. If the people in these camps sat still and never said a word about their mines; if they did not establish newspapers to disseminate news about them; if they did not write about them and talk about them, and tell people what they were and what they were expected to be, and generally "blow their own horns," then none of these camps would be one-quarter as much developed as they are now. Mines alone will not make a successful mining camp by any means. We all know lots of places where there are good mines, but no "boom" has struck them, and no attention is paid to them.

Every mining camp wants capital, and every mining camp wants—talk. The mines bring the prospectors, the prospectors make the talk, the talk brings the capital, and the capital brings the coin. Then the camp becomes a camp indeed.

The talk has been as potent a factor as the mines, the people or the capitalists. If it had not been for that, people would have gone elsewhere where there was talk. What is the use of good mines, if no one knows about them? Of what service is a camp that cannot get people to examine its mines?

In fact, we know of a number of instances where a camp has been made temporarily by talk alone, no mines worthy the name being there. But the examples serve to show the truth of the argument that talk exercises a potent influence in making mining camps.

Therefore let us hear from you. The way to talk to a good many people at once is to print what you want to say. To men in small and large mining camps everywhere we open our columns and extend an invitation to them to tell us about their claims and other people's claims; their prospects and other people's prospects; and those of the camp generally.

What you find time to write several thousand people will find plenty of time to read. This will create talk and help your prospect, your mine and your camp, in the end. When the camp is mentioned people will know about it. They will not suppose, from not having heard of it, that the camp was only discovered yesterday. They will recollect having read in the MINING AND SCIENTIFIC PRESS what you said about the mines, the roads, the timber, the water, the formation, the climate and all the points which you tell us about.

Don't wait then till "some day when you have time," but sit right down and send us a letter descriptive of the region you are in. Never mind about the spelling, or the writing, or the grammar, we can get plenty of that here. What we want is the news of the camp, and we will put it in shape for publication. Who speaks first?

On the Occurrence of Vivianite in Los Angeles Co.

[Written for the PRESS by HENRY O. HANKS, State Mineralogist.]

Among a set of samples from Brea ranch, Los Angeles county, sent recently to the State Mining Bureau by Mr. J. W. Redway, of Los Angeles, was one of dark color and earthy texture, containing small nodular masses of a beautiful pale blue color, which were examined and found to be vivianite, or hydrous phosphate of iron. This mineral, which is rare in California, is interesting as leading to the hope that other phosphates, so important as fertilizers, may be found at or near the new locality. There is a specimen of vivianite in the museum of the State University, which is said to be from a California locality; but, if my memory serves me, this is attended with some doubt. It is reported, also, at Young's hill, Yuba county, and near Oroville, Butte county, but no certain information has been obtained.

The Los Angeles mineral occurs with asphaltum at the well-known Brea ranch deposit. The specimen is marked, "Gangue and Country Rock."

The mass is a dark-colored earthy mineral, with streaks and veins of asphaltic substance, the whole being evidently the sandy desert soil blown over and cemented by the former by liquid asphaltum. The vivianite is in small inclosed nodules, never larger than a pea and generally smaller. The mineral is that variety known as blue iron earth or native Prussian blue. It is soft, pulvernlent; under the microscope, crypto-crystalline; before the blowpipe, whitens for an instant, then blackens and fuses to a black magnetic globule. It is wholly and easily decomposed by boiling hydrochloric acid; the solution reacts for iron, which, being separated, the solution gives precipitates with sulphite of magnesia and with molybdate of ammonia. In a closed tube, it gives much water.

The specimen has been numbered 3538, and placed in the State museum, where it may be seen.

The name, vivianite, was given to this mineral by Werner, after an English mineralogist, J. G. Vivian, who discovered it in Cornwall. When pure it has the following composition, as given by Dana: Phosphoric acid, 28.3%; protoxide of iron, 43.0%; water, 28.7%.

Academy of Sciences.

The regular meeting of the California Academy of Sciences was held on Monday evening last, President Davidson in the chair. The following were proposed as resident members: President William T. Reid, of the University of California, Prof. Henry A. Ward, Thomas Brown and M. H. Hecht, and for life membership, John F. Boyd.

Prof. Henry A. Ward read a very interesting paper on "Mammoths," referring more particularly to the *Elephas primigenus*. One specimen of this, as "restored" by Mr. Ward, and now on exhibition at the Mercantile Library hall, in this city, is 16 feet high, and whose length, including the forward curve of the tusks, was 26 ft. or more. The remains of the mammoth are among the earliest animal remains now found, and are noted by writers B. C. 300, who speak of their discovery. Some curious mistakes occurred among those who found the large bones of these animals, and mistook them for antediluvian giants. Such bones brought to ancient Rome were believed to form part of the skeleton of Pallas, and are recorded as being as high as the city walls, when set up erect. Later, at Lucerne, in Switzerland, such bones were exhibited as those of a man 19 ft. high. As late as Feb. 13, 1638, the same thing was done in France, and also Scotland rejoiced in the skeleton of an antediluvian giant 14 ft. high. Later, the mammoth was supposed to be the behemoth of the ancient Hebrew Scriptures. In 1696, the bones of one were collected, and mounted by learned professors and anatomists at Gotha, in Germany, who declared it was not an elephant, but the one they had was simply a *lusus naturæ*. It was finally reserved for that great French naturalist, George Cuvier, to dispel the darkness in January, 1796, when he boldly announced that all such bones were the remains of fossil elephants, differing from any now living upon earth. They have now been found all over the continent of Europe, in the pliocene and post-pliocene strata. In Asia there are vast quantities of such bones found on the northern limits of the continent, within the Arctic circle. Siberia, along the Yenesei and Lena rivers, emptying into the Arctic basin, the Liakow or New Siberian islands, and the bed of the Arctic ocean, crossed by the crew of the *Jeannette* in their retreat to land, all are said to be thickly covered with bones of this class, abounding in fossil ivory. Many huge masses of bones have been piled up by freshets from rivers running northward and emptying into the Arctic. Huge masses of this ivory are annually shipped to England and there cut and utilized in the arts and manufactures. The Yakouts, or natives of that part of Siberia, formerly supposed these enormous animals to be a species of huge moles, that lived and burrowed under ground, and because their remains were found beneath the surface, they thought they lived and died there. The word mammoth is a native Yakout word, meaning in their language "an animal that burrows under ground"—and the world has adopted it as a popular word. They are most abundant in the far north, and become less and less frequent as the distance from the Arctic basin increases. Prof. Ward thought their long black hair and thick skin would enable them to exist in a temperate and, perhaps, a frigid zone. A mammoth was discovered frozen in latitude 72°, near a river, with his flesh frozen, and skin in place. In 1772, in latitude 64°, on the river Lena, a whole rhinoceros was discovered. In 1799, a Tungusean fisherman discovered in latitude 70°, near the mouth of the Lena, a dark mass in a block of ice, but it was too deeply imbedded to get at it. In 1804, he returned to the spot and found the ice block rent and fissured. The perfect mammoth had fallen out by its own weight. The hide was heavy, and had over it thin but long black hairs. The Yakouts fed their dogs upon its fresh meat, and white bears and Arctic foxes also joined in the feast. Branches of the woody twigs of trees were found undigested in its stomach, when, in 1808, a British traveler and scientist visited the carcass. He collected the bones, took 40 lbs. of black hair and one side of its hide, which he transported fully 7,000 miles to St. Petersburg, where they were purchased by the Emperor Alexander for 8,000 roubles, and deposited in the Imperial Academy of Sciences there. They have since been set up, and pieces of the skin and hair have been donated to the Paris Academy of Sciences, and to the Royal College of Surgeons, in London. Prof. Ward said there were two hypotheses entertained by scientific men in regard to how these animals came there in such large numbers. One was the hypothesis of a complete change of temperature by a sudden cataclysm; and the other, the gradual depression of the land, continuing through ages. In Europe the mammoth seems to have been coeval with early man. On the tusk of a mammoth found in a cave at Dordogne, in France, is carved with a flint implement a good likeness of a mammoth. Their remains are found more or less on every continent except Australia, which many geologists consider of recent formation. All our American valleys appear to have had their great herds of such elephants, which have now disappeared from our soil. Nearly 30 different varieties have been found. In Missouri a stone arrow-head was found imbedded under the shoulder-blade of a mammoth now in the British Museum. At Racine, Wisconsin, was found an ancient drawing of a mastodon, certainly drawn from life by men. Over a bushel of chewed twigs and succulent branches were taken from the stomach of the one found in the block of ice at the river Lena.

Prof. Joseph Le Conte read a paper by himself and Prof. Rising, giving the results of investigations on the phenomena of metalliferous vein formation now going on in Lake county, at the Sulphur Banks mine. Some of the phenomena described were referred to in the MINING AND SCIENTIFIC PRESS of August 1, 1879, and also in the "Quarterly Journal of the Geological Society" of August, 1875. Recent developments in the mines, however, have given much better opportunity for observation than before existed. The paper was at some length, but very interesting, and we shall endeavor to obtain it for publication.

Prof. George Davidson presented some observations on the temperature of air and water at the Golden Gate. We shall publish the facts gained in this investigation.

Prof. Ward announced that his collection of casts, etc., was now on free exhibition at the Mercantile Library hall, on Bush street.

Ore Concentration.

As the necessity for working low-grade ores becomes more apparent on this coast, the benefits of concentration are more fully considered. If we can get rid of a heavy mass of gangue, and take only the comparatively valuable portion of a lot of ore, we can afford to transport and treat it, when we could not if the major portion of the gangue were not eliminated in the first place. As more people turn their attention to the subject of concentration, new ideas are brought to the study, and new machine result. We have this week two to consider, both of which have just been patented through the MINING AND SCIENTIFIC PRESS Patent Agency.

The first is that of Edward Stahl, of Prescott, Arizona, whose concentrator consists in a passage, or channel, in open relation with a series of chambers below said channel, having at one end an inlet for a stream or head of water, and at the other an outlet therefor, and having a hopper through which the ore is fed into the stream below.

He has a sort of long box or channel having different receptacles below its floor or bottom, all opening into it. At one end is the water pipe or cylinder which is high enough to obtain the required head of water. Into the top of the channel opens a hopper at the same end as where the water enters. Water is poured into the pipe, and the discharge end of the channel being smaller than the supply end, the said water fills the channel and rises in the hopper to the brim. This water fills all the chambers in which and in the hopper it is in a state of comparative rest. The current passes through the main channel, its exit being controlled by a gate. When the water is passing through and the hopper full the ore is fed into the hopper, where any light substances, such as chips, scum, etc., will float off. The ore sinks into the channel; here it encounters the current of the stream and portions of it are carried by it to different distances. By this means separation is effective. According to their respective densities they will be carried onward by the current, those having greatest specific gravity settling in the first of the series of compartments, and so on. The device may be made any length to suit the treatment of ore in hand. The limit to the capacity is the amount of water obtainable.

Another invention in this line is that by Joseph S. Duncan, of this city, which consists in the employment of a pan to which a rotary motion is given and at the same time a shaking or oscillating motion, whereby an advantageous effect is produced upon the auriferous earth and sand which are deposited on the pan over its outer edge. The earth, sand and water are put upon the revolving pan at its outer edge and fall into a channel there formed. The centrifugal force has a tendency to throw the heavier or precious particles to the extreme outer edge, while the oscillating motion of the pan settles them to the bottom. As the operation is continued and the material is constantly thrown up against the outer rim, the channel becomes filled with the precious particles, while the sand lies on top and is filled up against the rim, forming a downward grade to the center of the pan, and it can be easily drawn off at the center. A further advantage of this rotating pan is that the time it takes for the water to pass from the outside to the center, where it is wasted through the hollow king post, is increased, thus giving the particles time to settle from the water. If the pan were stationary the water would flow directly from the periphery to the center, and, having but a short distance to cover, would be likely to carry some of the precious particles with it and waste them; but by revolving the pan the water is forced to take a spiral course to the center and thus cover greater space, giving the particles time to drop out. As a consequence of this an increase in the volume of water is felt more gradually and there will be no rushing force to the center. Suitable arrangements are made for drawing off the precious metal. S-shaped flanges are placed near the center of the pan to break the force of the water, conduct the water to a central aperture and discharge it directly. Without them the water would not pass off easily. A protecting plate prevents splashing.

THE Northern Belle's reserve had been reduced to $47,569 on the 1st.

On Minerals.

[Notes of a Lecture delivered before the Mechanics' Institute by A. W. Jackson, Jr., Instructor of Mineralogy, Petrography and Economic Geology, at the University of California

(Continued from Last Week)

You will recogniza some of these minerals as I name them. The commonest and most important of all are the feldspars, with which you are familiar as the dall, white or red constituent of granite. It is the mineral which gives the beautiful red color to Scotch or Aberdeen granite. It is not only a constituent of granite, but enters into the composition (except of sandstones and limestones) of nearly every other important rock-mass on the face of the earth. It is so important that in determining the nature of a rock, about the first thing to be considered is the nature of the feldspar it contains. I speak of feldspar as a single mineral; the term really comprises a group of minerals, differing from one another to the extent that some contain potash, while others contain soda and lime in varying proportions; while all contain alumina. In physical properties, however, color, form, hardness, they resemble each other very closely, and they all play the same *role* in the make-up of the rocks. As a final product of their decomposition, we obtain pure white porcelain clay, the most essential raw material for fine porcelain.

Two other minerals or rather groups of minerals of this family, viz., the hornblendes and the augites are secondary only to quartz and feldspar as rock constituents. While the feldspars are always of a lighter color, these two minerals are dark green to black, and impart the dark, somber colors to syenite, basalt, and such rocks. Hornblende is the dark constituent of the Penryn and Folsom "granites," used in the S. F. Stock Exchange building, and the black blotches that here and there mar the polished surfaces are due to local aggregations of the granular of this black mineral.

Garnet and tourmaline are both members of this family, and both are familiar in that they furnish gems of somewhat inferior quality.

Red garnet is frequently seen in jewelry. A most exquisite emerald-green garnet was recently sent to the University museum from Auburn, in Placer county, that only needs to be found in somewhat larger crystals to become a valued gem. Its color is as clear and pure as that of the finest emerald. It may be looked for in the vicinity of chrome iron deposits. *Tourmaline* is of most complicated chemical composition, containing never less than 10, and sometimes as many as 16, different elements. It occurs in all colors, and is one of the few minerals that show pyro-electricity. The gems from garnet and tourmaline are inferior because of their inferior hardness and less brilliant luster. The true emerald and true topaz also belong here; both are inferior in hardness and lustre to the Oriental emerald and Oriental topaz. The emerald is the green variety of the mineral beryl, while the topaz is a simple silicate of alumina. The emerald, on account of its exquisite green color is most highly prized as a gem, while the topaz has rather gone out of fashion.

I will mention but two other minerals of this family, viz., nephrite and jade, and in connection with them, call your attention to the not unimportant assistance which mineralogy is beginning to render in the solution of ethnographic and anthropological problems, which, up to the present time, have been studied from the historical, linguistic and physiological sides only.

Jade and Nephrite

Are both green minerals, quite hard, and about the toughest substances known among the stony minerals. They were selected by the prehistoric peoples of New Zealand, Siberia, China, Mexico, Middle and South America for their stone implements and various other stone objects. In parts of China and Siberia they are still used for the same purposes. We can understand how it should be so in these countries and in New Zealand, because large deposits of the mineral occur within their boundaries. But, in spite of the fact that large numbers of prehistoric ornaments have been found in Mexico and South America manufactured out of jade and nephrite, not a single natural occurrence of these substances in North America or South America is known to-day. It is furthermore proven that the raw material of all of these American stone ornaments came from China; and, by means of the peculiar microscopical texture of the mineral from different localities, it is possible to point out the precise locality in Asia from which the raw material for any given American prehistoric nephrite or jade ornament was obtained. You at once perceive the significance of this fact, establishing as it does a connection between this coast and Asia that long antedates our present civilization. Mineral ornaments and objects are among the most imperishable records that have come down to us from the remotest antiquity, and the foregoing is but one of many instances that might be cited where a study of these records may throw light upon the early migrations of people or early commercial connections between different and perhaps widely separated peoples. Of the origin or mode of formation of the minerals of this family I will speak at my next lecture.

Zeolites.

The minerals of the family of scleritas contain no water. It is quite characteristic of the zeolites that they contain considerable water, which they readily yield up on being heated before the blowpipe, with a boiling motion, whence the name, from zeo, to boil. About 40 zeolites are known; they are mostly white or colorless, occur in beautiful crystals, very commonly in hollow cavities of rocks consisting of minerals of the previous family. They are formed from the *leachings* of these minerals and crystallize out from this water solution at the first convenient opportunity, viz., in the little cavities just mentioned. They occur rarely upon silver and copper ore veins, while the anhydrous silicates never occur there.

Micas.

The commonest micas are very familiar. They are the thin black and white scales seen in granitic rocks; that is altogether their characteristic mode of occurrence. These scales rarely attain the considerable size that fits them for use in the arts. Much of the mica used in this country is from the mines in North Carolina. These mines are really in exceedingly coarse-grained granite. In granite, as we ordinarily see it, the grain is very fine, and the mica scales useless. The constituents of granite, however, sometimes take on colossal dimensions. The feldspars and quartzes weigh tons, and the mica scales are 6 ft., more or less, in diameter. It is then, of course, possible to work it.

The familiar substance soapstone—so called from the smooth, soapy feel—is a mica, only the mica scales are too minute to be recognized as such by the unaided eye.

Finally, porcelain clay—the purest form of common clay—is also a mica. It consists entirely of minute, diamond-shaped scales, recognizable as such only under the microscope. It is formed from the total decomposition of the feldspars, and is the final insoluble residue after everything else has been dissolved out.

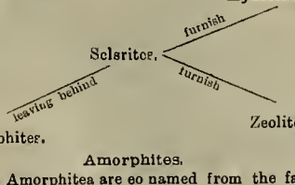
Amorphites.

You obtain the best conception of the minerals of this family if I tell you at once how they are formed. If you will observe any dark crystalline rock, like basalt, that has been exposed to the weathering action of atmospheric waters for a considerable period, you may notice along the cracks that fissure the rock in all directions, that the rock is *bleached*, has lost its color in immediate proximity to the crack; has turned, perhaps, perfectly white, the color gradually deepening as you recede from the crack into the mass of the stone, where it assumes its normal dark color. The cause of this change of color is the leaching effect of the atmospheric waters that I have already twice referred to.

Basalt is made up principally of feldspar, augite, olivite, and magnetite. These minerals contain soda, Na_2O; lime, CaO; iron, FeO; magnesia, MgO; alumina, Al_2O_3; and silica, SiO_2; while atmospheric drainage water, H_2O, contains, among other things, carbonic acid, CO_2, and sulphuric acid, SO_3. * * *

In a similar way most of the sclerites yield by atmospheric weathering, a process that extends through geologic ages, similar insoluble decomposition products.

You observe, then, the relation existing between the different families of silicates and the order of hydrolites:



Amorphites.

The Amorphitea are so named from the fact that they are devoid of crystal form. They are soft, dull, earthy, colorless, or colored by oxides of iron or manganese. They form an exceedingly important element of soils, together with clay, sand, oxide of iron and humus.

In the formation of soils which, you understand, results from the disintegration and degradation of rocks, the most insoluble and indestructible elements of the rocks, such as those above mentioned, must necessarily aggregate together. From their inconspicuous, earthy nature, they would naturally fail to attract the attention of the ordinary observer.

Under favorable circumstances, however, these amorphites may collect in quantity, tolerably free from clay, sand, oxide of iron, or humus. Two familiar instances of this sort are

Meerschaum and Rock Soap.

The former is sufficiently familiar; the latter mineral bears no passable name, as it really acts in many respects like soap, although, of course, it does not resemble it in composition, being a hydrated silicate of alumina. It can be mixed in nearly equal parts with ordinary soap without in the least deteriorating its quality.

Apyritites.

We come now to the last of the stony minerals, to those, namely, that, with all of the other properties of ordinary stones, are free from silica. We find here combinations of the same bases as above, with some *other* acid than silica, viz., carbonic, sulphuric, fluorhydric, phosphoric and some others. Many of them are quite familiar.

Thus fluor-spar, fluoride of calcium, is cut into ornaments in England, used as a flux in metallurgical works and furnishes a most powerful etching material, fluorhydric acid. It occurs on ore veins.

Calcite, or limestone, known in the arts as marbls, is found in all countries, and is used for the greatest variety of ornamental and useful purposes. It may be of interest to note the great difficulty which sculptors meet in obtaining sufficiently large blocks of marble absolutely free from crack or flaw and of spotless purity of color.

The Parian marble, from the Isle of Paros, and the Cararra marble, from Modena in Italy, famed even with the ancient Greeks, are to-day almost the only materials that can be used. One cubic meter costs $450. Burnt limestone furnishes quicklime, and a peculiar compact homogeneous limestone is used as lithographic stone. There is some possibility that Kern county may furnish this valuable material before long; at the present time it comes from Solenhofen, in Germany.

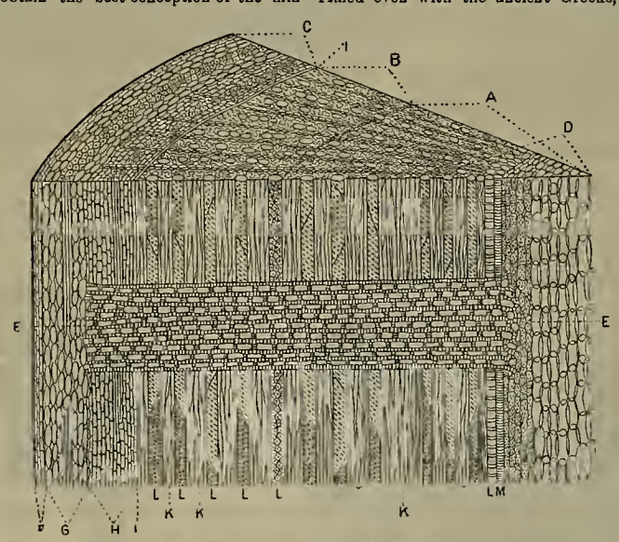
Aragonite is only another form of carbonate of lime. The Suisun marble and the Mexican onyx are both varieties of this mineral. They may be seen in the panels to the counters of the offices of Baldwin's hotel and the S. F. *Chronicle*.

Gypsum, a hydrated sulphate of lime, furnishes our plaster of Paris, and the phosphate of lime, phosphorite, is highly valued by agriculturists as a fertilizer.

The strontium and barium salts are used for colored flames in the art of pyrotechny.

One gem is found in this group—the beautiful blue turquoise, a hydrated phosphate of alumnium; it owes its color to a very small amount of copper. It occure in the form of small veinlets and nodules in quartzite in Persia, in sandstone in Egypt, and in a decomposed rock in Esmeralda county, Nevada. The best gems come from Persia. Those from Egypt change their color rapidly, while the Nevada turquoise has rather an unfortunate greenish blue color that renders it well nigh valueless as a gem. Still, I have seen good gems from there.

(To be Continued.)



SECTION OF TREE MAGNIFIED TO SHOW CELLULAR GROWTH.

The Bodie *Free Press* prints the following: "Several men have been at work off and on during the winter on the eastern slope of this ridge placer mining. When water could be obtained small wages were the result—enough to buy grub. The squaws occasionally make a clean-up of two or three dollars, but the manner in which they operate would not suit a white person. When it comes to patience, a Piute female excels a Chinaman.

The Bullion assessment of $30,000 now in process of collection, will still leave the mine in debt, as on the 1st it owed $20,431.

How Plants Grow.

As the swelling buds and shooting leaves betoken the approaching of another season of activity in our trees and plants, it will be timely to review the subject of plant growth, in order that all may be better able to trace the processes of nature, which culminate in the stalwart timber. To do this, we select paragraphs from a famous essay by Col. W. S. Clark, recently President of Amherst Agricultural College, in Massachusetts, borrowing both text and engraving from this source.

When ordinary cells are united into a more or less extended structure, they constitute what is known as cellular tissue. This may be soft and pulpy, as in the flesh of an apple, loose and tender as in the pith of an elder, firm and tough as in birch bark, or hard and brittle as in the shell of a hickory nut or the stone of a peach.

The tissue of the inner bark, consisting of very long and narrow cells overlapping each other at the ends, is called bast; and that of the stem, in which the cells are similar, but shorter, is called woody fiber. The tubes which are formed are styled ducts or vessels, and, as they are mingled with woody fiber in the annual growth of timber, the ordinary combination of these is named the fibro-vascular tissue.

When these enlongated cells and ducts are straight and parallel, as in the chestnut, the wood of which they are the warp splits easily, but when they are interlaced and blended irregularly, the longitudinal grain of the wood will resemble that of elm.

Every seed and every young plant consists wholly of cellular tissue, but with the development of leaves is combined the growth of fibro-vascular tissue.

The Progress of Growth.

The first vessels to appear in the plantlet are arranged in a circle around a column of tissue, which remains loose and soft, and after the first season dries up and dies. This is called the pith, and seems essential to the life of every woody branch and stem during its infancy, although its special function is unknown. Between the vessels around the pith may be seen the rays of cellular tissue, which ultimately become hard and firm, and which unite in bonds, never broken except by some external force, the inside of the stem with the inside of the bark. These rays make up the woof, and have much to do with the distinctive peculiarities of different sorts of timber.

Immediately outside the vessels inclosing the pith grows a layer of woody fiber, upon which, in a more or less developed state, according to season, is a layer of organizable material, called cambium, which may be regarded as the seat of life of the plant. Next to the cambium, and united to the wood by the rays from the pith, is the bark, consisting of three layers.

The inner or fibrous layer is formed by bast cells and firm cellular tissue. Surrounding the inner bark is a layer of cellular tissue, in which the rays from the pith terminate, and which is named the green layer, because it often exhibits this color in young shoots, and then performs the same function with the green tissues of the leaf. Outside of all this is the corky layer, consisting of dry, dead cellular tissue, and developed annually from the green layer. This is not usually of much thickness or consequence, but sometimes, as in the cork oak of Spain, it becomes an important article of commerce.

The growth of our trees goes on in the cambium layer, from which is produced annually a layer of wood and a layer of bark, each formed of longitudinal fibro-vascular tissue and horizontal cellular tissue.

The Engraving

On this page represents a section, both vertical and horizontal, of a branch of a sugar maple two years old, as it appears in December. The portion included in the lines marked A is of the first year's growth; those marked B indicate the wood of the second year; while those marked C inclose the three layers of the bark. D represents the pith of loose cellular tissue; E, the pith rays or silver grain of hard cellular tissue connecting the pith with the green or middle layer of bark, which also consists wholly of cellular tissue; F marks the outer or corky layer of the bark, which is composed of dry, dead cells which are formed of consecutive layers from the outer portion of the living green layer; G is the green layer or cellular tissue; H shows the liber or inner bark, made up of cellular tissue, penetrated by long bast cells arranged parallel with the axis of growth; I represents the place of the cambium or growing layer of organizable material which descends from the leaves between the liber and the sap wood during the period of growth; K is woody fiber which gives strength to the stem, and through which the crude sap rises; L indicates the vessels or ducts, with various markings, such as dots, rings and spirals, which are formed abundantly in the spring, and usually contain no fluid. They convey gases and aqueous vapors, and it may be that a large proportion of all the water ascending from the roots to the leaves passes through them as vapor. M is the layer of spiral vessels or ducts which always inclose the pith, and in the young shoot extend into the leaves and unite them to the pith during its life, which ceases with the first season.

CHICAGO **FRASER & CHALMERS,** ILLINOIS.

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail.

HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,750 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x30 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. BOILERS of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

HOISTING ENGINES Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. P. Haggin for Giant and Old Abe Co., Black Hill s also Corliss Pumping Engines, 26x60, for Hoisting and Pumping Works, for 2,000 feet deep. **Baby Hoists for Prospecting, 4 H. P. to 6 H. P.**

Wire Rope, Safety Cages and any Size and Forms of Cars. McCaskell's Patent Car Wheels and Axles—Best in Use.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois. New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street - - San Francisco, Cal.

DEWEY & CO.'S

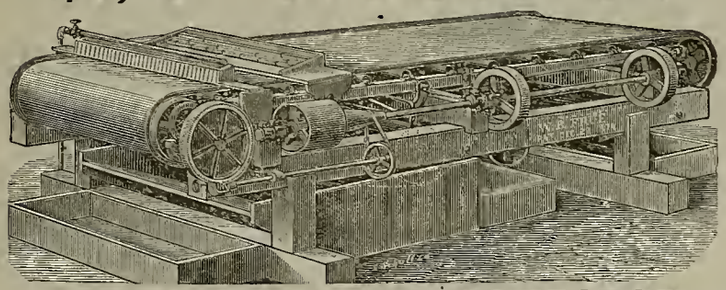
Scientific Press **Patent Agency.**

[ESTABLISHED 1860.]

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 252 Market St., S. F.

A. T. DEWEY. W. B. EWER. GEO. H. STRONG.

$1,000 CHALLENGE!



THE FRUE ORE CONCENTRATOR.

Nearly 300 are now in use, giving entire satisfaction. Awarded First Premium and Silver Medal at the Industrial Fair for 1880 of the Mechanics' Institute of San Francisco, Cal.

Saves from 50 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal; water required is less than in any other wet Concentrator; the power required per machine is less than one-half horse power; the labor required is light, one man on a watch can attend to sixteen machines.

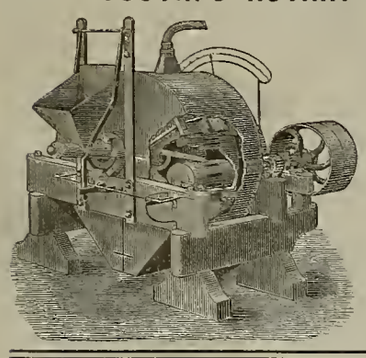
We challenge any other Concentrator in use for a fair and impartial competitive trial, side by side, for stakes of $1,000 each, and we mean business.

☞A machine with all improvements can be seen in working order and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont street.

ADAMS & CARTER, Agents, Room 7 No. 109 California Street, S. F.

TONITE POWDER COMPANY, - - 403 California St., S. F.

TUSTIN'S ROTARY PULVERIZING MILL.



WORKS ORE WET OR DRY,

And Feeds Itself Automatically.

Patented October 11, 1881.

One of these machines can be seen at the Ore Sampling and Pulverizing works of Hofmann Bros., No 415 Mission St., where it is working every day. Weight 5,000 lbs., heaviest piece 480 lbs.

Manufactured at the

TUSTIN WINDMILL, HORSE POWER AND PUMPING MACHINE WORKS.

308 Mission Street, S. F., Cal.,

By W. I. TUSTIN, Inventor and Patentee.

ENGINE LATHES IN SECTIONS.

Limit of weight for 25-inch Lathes, 300 pounds. For 17-inch Lathes, 150 pounds.

Standard and Special Machine Tools.

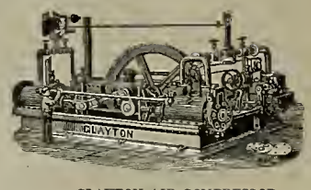
SAN FRANCISCO TOOL CO., No. 21 Stevenson St., San Francisco.

CLAYTON AIR COMPRESSORS,

—AND—

INGERSOLL ROCK DRILLS.

INGERSOLL ROCK DRILL.



CLAYTON AIR COMPRESSOR.

Having been appointed Sole Agent for this Compressor, I will keep a full stock of the different sizes in store. Prices much less than any First-class Compressor in the market. ☞SEND FOR CATALOGUE.☜

GEORGE R. FOARD, 18 First Street, S. F.

Sole Agent for the Ingersoll Rock Drill and Clayton Compressor Co.

VULCAN BLASTING POWDER.

—THE MOST ECONOMICAL AND BEST—

Nitro-Glycerine Explosive in the Market.

In the suit of the Giant Powder Co. against the Vulcan Powder Co. for *alleged* infringement of Patent, it was held that the Giant Powder Patent was INVALID.

Nos. 1, 2 and 3 Vulcan,

Each grade superior to like numbers of any other Nitro-Glycerine Powder in the market.

VULCAN B. B.,

Superior to Black, Judson or any low grade Powder for Bank Blasts, Railroad work, or any work where Black Powder has been heretofore employed.

TRIPLE FORCE CAPS AND ALL GRADES OF FUSE.

The CONSUMER'S COMPANY sell the best Powder at the lowest rates.

Office—218 California St., San Francisco.

Metallurgy and Ores.

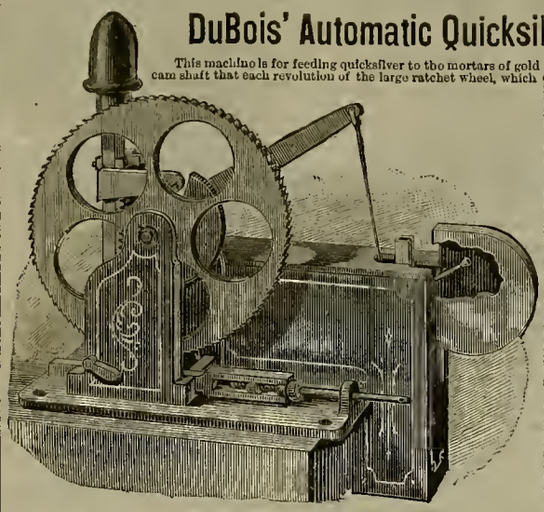
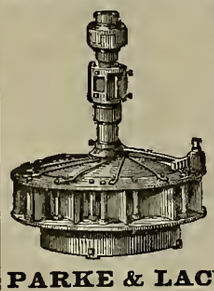
Manufacturers of
THE PATENT CHANNEL IRON WHEELBARROWS.
THE STRONGEST BARROW MADE. These Barrows are made by Superior Workmen, and of the best material. All sizes kept constantly on hand
SHEET IRON PIPE.
Lap-Welded Pipe, all Sizes, from Three to Six Inches. Artesian Well Pipe. Also, Galvanized Iron Boilers, from 25 to 100 Gallons.
Iron Cut, Punched, and Formed for making Pipe on ground, where required. All kinds of Tools supplied for making Pipes. Estimates given when required. Are prepared for coating all size of Pipes with a composition of Coal Tar and Asphaltum.
Office and Manufactory, 130 Beale Street, San Francisco.
SHEET IRON PIPE.

DuBois' Automatic Quicksilver Feeder.


This machine is for feeding quicksilver to the mortars of gold mills. It is so connected to the cam shaft that each revolution of the large ratchet wheel, which can be regulated to revolve once in one, two, three or four minutes, as desired, dips a small cup into a reservoir of quicksilver, and by a trip of the cam, empties the contents into a pipe leading down to the mortar, supplying an exact quantity at regular intervals, superseding the ordinary hand feeding, which is of necessity subject to great irregularity, and liable to neglect. It renders the amalgamation of all the gold in the pulp equally certain and perfect.
The mechanism to produce this depression and elevation of the cup, is driven by the cam shaft, similarly to the self-feeders, over which so much ingenuity has been expended to regulate the delivery of ore to the mortar. As it is to be desired to have the ore go in constantly and regularly, so it is equally desirable to have the mercury fed constantly and regularly.
A chief point of excellence of this machine is, that it allows the quantity of mercury which would be otherwise fed in mass, in one hour, to be subdivided into a number of small portions, and fed almost continuously; *i. e.*, from every one to four minutes.
Price, complete, $100.
For Sale by **WHITNEY & MARSHALL,** Sole Agents
22 & 24 Fremont St., San Francisco.
Dealers in Iron, Steel, Hardware and Mining Supplies, Wrought Iron Pipe and Fittings, Pump Columns, Wire Rope, etc. A large stock of Boiler, Plate and Sheet Iron of every description.

MOREY & SPERRY,
MANUFACTURERS OF
Gold and Silver Grinding and Amalgamating Machinery
HOWLAND'S PULVERIZER Takes the Place of the Cumbersome Stamp Mill and can be put up in one day ready for work.
IT HAS BEEN FULLY PROVED AND TESTED.
It weighs complete, 7,000 pounds It costs $1,500 ready for the belt Will crush one ton per hour of hard quartz that will pass through a 40-mesh screen. The wear is less than in the stamp mill. Its wearing parts are plain castings and can be dropped into position in a few moments, as shown by the letters A, B and C, no bolts or keys are required; it can be set upon the floor of a mill with no expense for foundations, and can be used to crush and work in charges or continuous. It will amalgamate either gold or silver ores, making a simple, cheap and effective mill, it requires twelve-horse power.

Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver ores Chloridizing Furnaces, Retorts, Rock Drills Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies Iron Work complete for Wood Frames, also
SPERRY'S WROUGHT IRON FRAME FOR STAMP MILLS.
☞Great saving in time and money over the Wood Frame. It is made complete with Wrought Iron Frame ready to put upon the foundation. We construct Mills with Stamps weighing from 350 to 900 pounds for Gold and Silver Ores. Wet or Dry Crushing Mortars.
MOREY & SPERRY—Warerooms, 92 and 94 Liberty St., N. Y.

LEFFEL'S IMPROVED WATER WHEEL.


PRICES REDUCED!
PATENTS REISSUED 1868.
The "OLD RELIABLE" with improvements, making it
THE MOST PERFECT TURBINE NOW IN USE.
Comprising the **Largest** and the **Smallest** Wheels, under both the **Highest** and **Lowest** head used in this country. Our new Illustrated Book sent free to those owning water power.
Those improving water power should not fail to write us for **New Prices**, before buying elsewhere. New Shops and New Machinery are provided for making this Wheel. Address

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

From the official list of U. S. Patents in DEWEY & Co.'s SCIENTIFIC PRESS PATENT AGENCY, No. 252 Market St., S. F.

FOR THE WEEK ENDING FEBRUARY 28, 1882.

254,269—SLAB OR BLOCK FOR PAVEMENTS—Calvin Brown, Vallejo, Cal.
254,270—GRAIN SEPARATOR—J. Brush, Albany, Org.
254,309—STEAM CYLINDER AND PISTON—W. Hanna, Gilroy, Cal.
254,151—PIPE COUPLING—E. Nunan, S. F.
254,173—ORE CONCENTRATOR—Edward Stahl, Prescott, A. T.
254,177—FEEDER FOR THRASHERS—M. Thomas, Jr., Gilroy, Cal.
254,246—CATTLE CAR—H. Townsend, Alameda, Cal.
254,123- ORE CONCENTRATOR—J. S Duncan, S. F.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

FEEDERS FOR THRASHING MACHINES.—Massey Thomas, Jr., Gilroy. Dated Feb. 28, 1882. No. 254,177. This invention relates to that class of agricultural implements knows as "feeders for thrashing machines," which are used to receive the grain and straw placed upon them by the derrick, and which sustain the elevator upon which the straw is raked or held down, and by which it is carried up to the self-feeder, preparatory to being fed into the thrashing cylinder. The usual operation of feeding grain and straw to a thrashing machine consists in forking it from the stacks by means of a derrick and depositing it upon the forward end of the derrick wagon. It is then held down by hand upon the elevators, which carriee it up to the self-feeder, by which it is fed to the thrashing cylinder. This invention has for its object the employment of mechanism to feed the grain and straw to the elevator, and, by a proper construction thereof, so regulate the feed as to dispense with direct manual labor or hoeing it down, and feed regularly and properly to the self-feeder above, thus assisting the self-feeder and aiding the whole operation. Its object is separate from that of the self-feeder, the latter being used to feed to the cylinder, and having to receive its own supply from a source regulated by hand, and, consequently, all the regularity and separating out must be done by itself, while the former is used to precede the operation and feed to it with the regularity and precision of mechanism, instead of employing manual labor.

ORE CONCENTRATOR.—Edward Stahl, Prescott, Arizona. No. 254,173. Dated, Feb. 28, 1882. This patent we refer to more fully in another column.

ORE CONCENTRATOR.—J. S. Duncan, S. F. Dated, Feb. 28, 1882. No. 254,123. We have described this patent in some detail in another column of this number of the PRESS.

GOLD AT STAMPEDE GAP.—It is proven beyond a doubt that deposits containing gold exist out at Stampede gap. Exceedingly rich specimens brought in from there substantiate this fact. Rock from there exhibited on the street was "lousy" with gold. The yellow metal was first encountered in the First Chance mine, and not the Ontario, as stated by us last week. The First Chance, like all the mines in that locality, until lately, was an old, abandoned prospect, and a few days ago was relocated by Tom Brown, Thomas and another man. The ledge is from 8 ft. to 12 ft. in width, and is composed of iron and quartz. Old prospectors, who prospected at Stampede in '70, used to express the opinion that gold existed in that country, and developments prove them correct in their opinion.—*Pioche Record.*

LIEUTENANT A. H. PAYSON has assumed charge of the lighthouse department for this city and moved the office into the Government building on Sansome street. He relieves Lieutenant-Colonel S. C. Stewart, who took charge of the office as a successor of Colonel Williamson when clerk Best was charged with forgery.

UNDER the decision of the Postmaster-General it is understood that all mail contracts in California for which Boone, Salisbury and Cahill, members of the straw bond ring of contractors, were the lowest bidders, will be withheld and readvertised or awarded to the next lowest responsible bidder.

IT is proven beyond a doubt, says the Pioche *Record*, that deposits containing gold exist out at Stampede gap. Exceedingly rich specimens brought in from there substantiate this fact. Rock from there exhibited on the street was "loney" with gold. The yellow metal was first encountered in the First Chance mine,

The Debris Suit.

The arguments in the debris suit have nearly been concluded. On Monday, A. P. Catlin spoke on behalf of the defendant. His argument thus far has been wholly a review of the testimony relative to the question of whether the material of the defendant's mins comes down or not. He holds that the testimony shows that the matter in the lower river is that which the early mines, from 1849 to 1869 placed there, and that all the damage claimed was the result of that material being brought down by the flood of 1861-2, and some little by subsequent floods; that the difficulties of navigation in the Sacramento river culminated in 1875, and that ever since, the navigation has been improving; that the material from the defendant's mine impacts in the American river and remains there, and ever will, a saving exception being made only as to the work of ages to come, concerning which no man may pronounce.

Judge W. T. Wallace, on Tuesday, opened for the defendant. He said that California in 1850 erected this into a State before admission was obtained to the Union. The statutes of 1854 are a memorial of that usurpation. The discovery of gold brought a population here with no idea of agriculture, being only in search for gold. What was to be expected from such a gathering? They gave law to the land; they did not wait to pass through the territorial gate, but sprang over the wall; the people claimed to own California and demanded admission to the Union; they borrowed large sums for their Government, levied taxes, adopted a seal and passed a law to regulate mines, to declare certain streams navigable and to declare against obstructions in the same; but no one dreamed then of mining being in any way an obstruction to the rivers; Sacramento was the child and favorite of the miners for the Capital; then came the admission to the Union and the act to allow miners to make local regulations, thus giving them back a part of the legislative powers; then the act giving to the miners the right to enter upon agricultural lands to mine, on giving a bond; and then the act to exempt miners from taxation; then the act allowing miners to take lands, and then the Drainage act. These were manifestations of power and the policy of it. That the two last acts are unconstitutional does not weaken the illustration.

He cited many cases showing that the courts recognized the rights of miners, under the customs and policy of the State, to appropriate waters, divert and work the streams, etc.; also, cases showing that local mining customs, according with the policy of the State, should be supported.

Custom is the best interpreter of the law. What is done under the law without complaint, is the law. As to reasonable use, it is an integral part of the law of riparian rights. He reviewed the Maryland cass, where one was held for putting into a stream a little blood once a week, and said it was in direct conflict with the case of Keyes vs. The Little York Company, in the Supreme Court of California. The California case is the better law, he said. As to Governmental control of the streams, they were given in trust to the State for commerce. Now gold production has a closer relation to commerce than navigation, which is but a means to commerce. It is a serious question when Congress will say: "Shall the navigation of the Sacramento river be preserved, or shall it be let go in favor of all the gold behind the mining interests?" He wished to be understood as holding no such view himself, but that is what a disinterested Eastern Congressman might say.

In all the butcher and tallow cases cited, the business was not destroyed; they were simply told to move on to a more convenient point. Here the mine cannot be moved on; to stop it, is to destroy it; this is an information and concerns only the rights of the State, and not of any private relators; hence, the Court cannot consider private damages. The hill proposes to practically disorganize seventeen counties, prevent the taking out of $1,000,000,000 to $2,000,000,000 of gold, and to relegate to poverty 150,000 people. The evil complained of is capable of a remedy; all the engineers agree as to that, and one dollar in four hundred will pay the cost of it. The mines will pay all the cost if once given the power. They have not now the power to condemn spots, nor build restraining works or do the needed work. Stopping the mines will not check the advancing wave of debris. So said the Governor in his message, and so say the engineers. Draw a constitutional hill and pass it; give the power to apply the remedy and put the whole burden where it belongs—and that is, on the miners. If the miners are worth all they say, they can well bear the expense.

Counsel then attached the authority of the Attorney-General to bring the suit and cited authorities against his claim. Is the Attorney-General the Attorney-General for but two-thirds of the people, or for all? Where is the Attorney-General for the one-third of the people sued here in their own name? The power exercised here is one for the Legislative, not the Executive Department, to which the Attorney-General belongs.

At the afternoon session, Attorney-General Hart opened his closing argument for the plaintiff. He spent nearly two hours in defending his action as Attorney-General in bringing the suit, citing a great number of authorities.

News in Brief.

EGGS sell for $1.50 per dozen at Hailey, Wood River.

IMPORTANT arrests of Nihilists have been made at Odessa.

THERE are serious signs of a movement among the Poles.

THE Oswego Iron Works, Oregon, turn out about 18 tons of iron a day.

SINCE the flooding of the Gold Hill mines, the flow of water through the Sutro tunnel has been considerably increased. It now averagee 7,205,933 gallons per 24 hours.

THE back water from the Mississippi river extends up the White river to Clarendon, Ark., a distance of 135 miles from the mouth. The entire country intervening is under water.

BY the explosion of a barrow of matte, John Raher, an employee of the Montana Copper company, at Meaderville, M. T., was severely burned about the head and face last week.

MILTON S. LATHAM, formerly Governor of, and U. S. Senator from, the State of California, died in New York this week. He was an old Californian, well known all over the coast.

THE Tucson, A. T., gas works are nearly completed, and the city will be lighted on the 25th of March. The works will cost $120,000, and will have a capacity of 32 000 feet of gas.

THE recent rains brought the long wished for freshet to the streams in Mendocino county, enabling the lumber men to send down their logs. Many thousands were floated down to the sea.

REFUSE cedar is likely to become of market able value. Puget sound loggers have been instructed to forward all the refuse cedar that can be obtained, in consequence of a sudden demand for that kind of lumber in South America.

IN a communication of the Secretary of War to the Senate, a letter from General Sherman is enclosed, in which he says that four-fifths of the army have been for the last 10 years engaged west of the Mississippi, looking after Indians.

THOMAS B. H. STENHOUSE, San Francisco correspondent of the New York *Herald*, died in this city on Tuesday. At one time in his life he was a resident of Utah, and a Bishop in the Mormon Church. Mr. Stenhouse was well known on this coast.

PANAMA advises to the 26th ultimo say: The American Bark, *Legal Tender*, is in port with a cargo of redwood lumber from Eureka, Humboldt county, Cal. There is a good demand for redwood lumber of all kinds, as it is very durable, does not shrink, and the ants, which destroy almost all varieties of pins lumber and timber, do not touch it.

A SUCCESSION of earthquakes occurred at Merced Monday. They continued a number of seconds, and were so heavy as to cause an unceremonious adjournment of the Superior Court in the midst of an important criminal trial, the judge, jury, attorneys, officers and prisoners rushing pell-mell down stairs and out into the court-house yard. At 1:57 two quite severe shocks of earthquake were felt at Santa Cruz, lasting several seconds. Shocks were also felt at Gilroy, Monterey and Watsonville.

PERSONS receiving a sample copy of the MINING AND SCIENTIFIC PRESS *with this notice marked*, are requested to examine the merits of the same, and consider fairly its claims for support, and if consistent, subscribe for the paper through the P. M. or agent delivering it, or otherwise. We shall send it, on trial, at the rate of $4 per annum for any period the reader may wish. Please notice our terms elsewhere, and if desired, send for further samples and information. Those who can circulate this No. further to our advantage are invited to do so.

A TURNED LEAF will point out the article supposed to be of special interest to persons receiving sample copies of this paper.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

BOUND VOLUMES OF THE PRESS.—We have a few sets of the back files of the MINING AND SCIENTIFIC PRESS which we will sell for $3 per (half-yearly) volume. In cloth and leather binding, $5. These volumes, complete, are scarce and valuable for future reference and library use.

CORRESPONDENCE on mining and other subjects represented by this journal is solicited from all reliable sources. Send us information, early and often, if ever so brief.

BY TELEPHONE.—Subscribers, advertisers and other patrons of this office can address orders, or make appointments with the proprietors or agents by telephone, as we are connected with the central systemin San Francisco.

THE State Mining Bureau, No. 212 Sutter street, is open to the public from 10 o'clock A. M., to 5 o'clock P. M daily, (Sundays excepted). Henry G. Hanks, State Mineralogist.

Cylinder Printing Press for Sale.

A large cylinder Hoe printing press, for country newspaper work, can be bought cheap by addressing

Press, Box 2361, S. F.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

Several first-class styles, good as new, will be sold at a bargain. Call on or address H. F. D., at this office.

Pleasure in Recommending, Etc.

OAKDALE, Stanislaus Co., Cal., March 6, 1882.

Messrs. Dewey & Co.—DEAR SIRS:—I hereby acknowledge receipt of patent with copies, for which please accept my sincere thanks. I shall take pleasure in recommending your agency when I have an opportunity.

Yours Truly, J. M. NELSON.

Mining and Scientific Press.

THE MINING AND SCIENTIFIC PRESS is the leading mining journal in America, and enjoys a larger circulation among the more intelligent operators and workers in the gold fields of the world.

Established in 1860, it has firmly maintained its position as a reliable, progressive journal. The information given in its columns has saved millions of dollars to the practical miners, metallurgists, mill men, mine and shareholders on the Western side of our continent.

Among its contributors are the ablest and most experienced mining engineers, superintendents and practical miners in this country.

The PRESS gives a condensed summary of Mining News from the most important mining districts of the country.

New processes and methods of mining are described in its weekly issues. New mining machinery and improvements are frequently illustrated and explained in a manner to be of great value to all interested in mining.

As a scientific and mechanical representative of the Pacific coast it is decidedly popular, and a standard journal with the most thrifty industrial people of the Pacific States and Territories. Its authority is of the highest order, and its usefulness in its special sphere unrivalled.

Every public library, mining engineer, metallurgist, mining operator and intelligent mechanic and manufacturer, will find profit by its reading.

Subscription, $4 a year in advance. Sample copies postpaid, 10 cents.

DEWEY & CO., Publishers.
No. 252 Market St., San Francisco, Cal.

Dewey & Co.'s Patent Agency and Newspaper Offices.

Dewey & Co.'s Patent Agency and the business offices of the Mining and Scientific Press, Pacific Rural Press, Pacific States Watchman and the Fraternal Record are now orably situated at No. 252 Market Street. Elevator entrance, *No. 12 Front St., S. F.*

Canvassing Agents.

We want several canvassing agents who will make it their business to solicit subscriptions and advertising for our first-class progressive newspapers. Men of ability and experience can secure good pay and permanent employment. Send references and state your past occupation, etc., to the publishers of this paper.

Business Offices and Sunny Rooms to Let.

We have some desirable rooms to let adjoining the offices of this paper which will be rented on favorable terms. Stair entrance, No. 252 Market St. Elevator, No. 12 Front St. Parties wishing offices, etc., will do well to call and see them. DEWEY & CO.

VIGORIT POWDER.

NO ACCIDENT HAS EVER HAPPENED.

ALL POWDERS manufactured hy the California Vigorit Powder Co. are SUBMITTED during ths course of manufacture TO SCIENTIFIC and accurate TESTS for safety and strength.

They are teeted for Safety against Friction, Fire, a Temperature of 212° Fahr., and the various ehocks to which Powder is liable in practical handling.

The following qualities are common to all grades of Powder manufactured hy the Company:

Safety; Non-Leakage; Freedom from Noxious Gases; Uniformity and Strength.

If consumers desire it, the EXACT STRENGTH of any Powder shipped to them will he GIVEN IN FOOT POUNDS. ☞ Send for Pamphlet showing methods of testing the different qualities of all Powders.

The Company manufactures:

DETONITE.

This is an explosive involving new principles and recently patented. It is the **Strongest Powder ever placed on the Market,** in this country or abroad. It is the **Safest Strong Powder ever made.** For very refractory rock this Powder is the most economical in the market.

VIGORIT. NO. 1, XX.

This Powder is **Stronger than the Highest Grades of Hercules or Giant.** It is only surpassed by "Detonite." It is suitable for hard rock.

VIGORIT, No. 1.

For general work this Powder has no superior. It has the advantage over Giant, Hercules or Vulcan in safety and freedom from noxious fumes.

VIGORIT, No. 2.

Equal to any corresponding Grade in the Market.

LOW POWDER.

VIGORIT, L. P.

This is a Powder suitable for **Bank Blasting, Log Splitting** or the work generally in which Black Powder can be used. It is STRONGER THAN BLACK POWDER, having from twice to ten times the effective strength, depending on resistance. It is **Superior to Judson Powder,** in being more sensitive to the cap and more convenient in handling.

Best Qualities of FUSE and CAPS sold at Lowest Ratee

SAN FRANCISCO, SATURDAY, MARCH 18, 1882.

VOLUME XLIV Number 11.

Waste of Sulphur in Precipitating Silver.

The quantity of sulphur required for the precipitation of silver is really only as 16 to 108, but a great waste occurs in the process from two causes. These are given by C. H. Aaron, in his treatise on the "Leaching of Gold and Silver Ores." Firstly, there is always a certain quantity of base metal dissolved with the silver, which also takes its portion of sulphur from the calcium sulphide; secondly, a large proportion of the sulphur is thrown down in a free state, and, in the usual course of procedure, is totally wasted by being burned off in the roasting of the precipitate.

The reason for this precipitation of free sulphur is, that the precipitant is necessarily a pentasulphide, for the calcium mono-sulphide is insoluble, and the bisulphide is only soluble with heat (*vide Regnault*), so that for our purpose we are restricted to the pentasulphide. But in the precipitation only one-fifth part of the sulphur of the pentasulphide can enter into combination with the silver, forming silver sulphide, and as the calcium combines with the oxygen and hyposulphurous acid, which were combined with the silver, the remaining four-fifths of the sulphur are unoccupied and useless.

Base metals, when present in the solution, act similarly, combining with only a portion of the sulphur of the pentasulphide, only arsenic and antimony forming pentasulphides. Gold forms tersulphide, but its quantity is usually insignificant in the lixivium.

There are two methods by which the free sulphur may be recovered from the precipitate. The first was introduced by Ottokar Hoffman, it is believed, which consists in subjecting the mass to heat in a retort, and condensing the sublimed sulphur. The second, original with Mr. Aaron, is as follows: The unwashed precipitate is placed in a vat with water, boiled by means of a jet of steam, and slacked lime carefully added. The free sulphur combines with the lime, producing at once on the precipitating solution of calcium polysulphide, and much more quickly than when the first sulphur is used. The boiling can be done in a filter vat, and when finished the clear solution can be drawn off. The precipitate is washed by running hot water through it, dried and roasted as usual. Three fourths or more of the sulphur is thus recovered for use.

THE Lake Valley (Sierras) Company, New Mexico, has 250 carloads of machinery, supplies, etc., on the way to the mines from California, including the best $80,000 mill, smelters and water-power. The company will bring water three miles, and probably have 500 men at work at an early day. The Colorado Smelting Company, with Governor Tabor at the head, will soon have a 60 ton concentrator there.

A CONTRACT has been let for the delivery of 6,000 tons of ore from the Morning Star mine during the months of March, April and May. This mine has paid five dividends, amounting to $365,000, and had a value of $50,000 worth of ore in the hands of the smelters at the close of February.

Arctic Geography.

The events connected with the cruise of the *Jeannette* have, within the past year or two, attracted more attention to the question of Arctic research than ever before. In this country, particularly, greater interest has been manifested in the geographical problems sought to be solved than was supposed would be the case. While the unfortunate ending of the *Jeannette* expedition has caused many to think that such expeditions are useless, yet all feel an interest in Arctic matters not formerly so noticeable.

The cruise of the revenue cutter *Corwin*, Capt. C. L. Hooper, in the Arctic ocean, to which we have before referred in these columns, developed some facts of more than passing moment. From Capt. Hooper's report we take the following description of Herald island, with a sketch by Dr. I. C. Rosse, surgeon of the *Corwin:*

HERALD ISLAND, IN THE ARCTIC OCEAN.

On the morning of the 20th our reckoning placed us to the northward and eastward of Herald island. We stood in to the ice, and, after following its edge to the southward for a few miles, made the land through a break in the fog, bearing northwest (magnetic), distant about ten miles. We hauled up for it and entered the ice, which was quite open on the edge, and steamed in about six miles, where we were stopped by a solid barrier of unbroken ice extending nearly north and south, and from 12 to 40 ft. in hight.

After examining the island (which was only three or four miles distant) very carefully with the glass, and assuring ourselves of the impossibility of there being any human inhabitants, we worked our way back to clear water.

The sides of this island are perpendicular cliffs 800 ft. high, and its top, which was then covered with clouds, is said to be about 1,400 ft. in hight. Capt. Kellett, R. N., who discovered it, and who succeeded in getting a foothold on a projecting rock, says:

"The island on which I landed is 4½ miles in extent, east and west, and about 2½ miles north and south, in the shape of a triangle, the western end being its apex. It is almost inaccessible on all sides, and a solid mass of granite. * * * The extent we had to walk over was not more than 30 ft."

The icy barrier which we found surrounding the island had the appearance of being unbroken, and I am convinced that it was not of a recent formation. I have questioned the whalers closely in regard to it, and find that none of them went west of Herald island last year. I am of the opinion that the ice did not leave it, and that it is no unusual occurrence for the ice to remain two and even three years without leaving the island free. I believe, moreover, that the ice rarely breaks up between Herald island and Wrangel's sound.

After getting clear of the ice we steered to the southeast, and in the afternoon fell in with and boarded the bark *Fleetwing*, of New Bedford, working up toward the island.

While cruising in this vicinity we hauled the dredge several times; but, as on previous occasions, found the bottom very barren of life, a few minute radiates and mollusks and some pieces of broken shells being the only things brought up. The bottom consisted of blue mud or pebbles, and particles of broken shells, according to location. The soundings were found to agree very closely with those given on the chart.

While in the vicinity of Herald island, a small land bird resembling a snipe flew on board. It was caught and caged, but died in a few hours, and was put into alcohol for the Smithsonian Institution.

The Dust of Cities.

At a meeting of the San Francisco Microscopical Society this week, Mr. H. G. Hanks, State Mineralogist, read the following paper:

In passing through Montgomery avenue, on my way home, I have often noticed quantities of dusty matter drifted into winrowe by the wind. In boisterous afternoons it is blown about, changing its position continuously. In rainy days it assumes the form of a dark-colored mud. Thinking it might contain the organic germs claimed by Tyndall to be inherent in dust, and particularly so in the dust of cities, I had the curiosity to collect a portion, which I submitted to chemical and microscopical examination with the following result:

Placed on the stage of the microscope under a low power, as taken from the street, it presents a disgusting appearance. The most noticeable constituents, as observed, were vegetable fiber, principally horse manure, and the decaying debris of Oregon pine and redwood planking, mixed with bits of coke and coal, broken glass, horse hair, quart sand, some blue particles, the nature of which could not be determined, and a dark-colored, finely-divided, half-dried mud, which was neither pleasant to the sense of sight or smell.

Burned in a platinum crucible the thoroughly mixed mass gave off a little water, a pale yellow flame and a disagreeable odor. On continuing the heat to incineration there remained in the crucible a ferruginous red-colored ash. The loss was 26% which was mostly organic matter, the sample having been previously dried in a steam bath. The ash was boiled in hydrochloric acid, which dissolved much iron. The gray residue was examined under the microscope with a two-thirds objective, and was found to consist almost wholly of angular quartz fragments, the result, probably, of crushed quartz sand.

A portion of the original substance was then treated with distilled water, which was previously boiled to destroy any organic forms that might be contained in it. Immediately on the water cooling, it was poured over the dust in a clean bottle, which was set aside for microscopic examination. The solution, or rather muddy mixture, was inexpressibly filthy and vile, but on examination microscopically, no living forms were observed. In six hours it was again examined and found to be alive with monads; in twenty-four hours, and again in forty-eight hours, a high power showed the liquid to be teeming with living forms, both animal and vegetable, being an interesting study to the microscopist. I noticed one animalcule in particular which I did not find figured in the books, and which I have never observed before. It somewhat resembles the vibriones, but it is more sluggish in its movements. When highly magnified it resembles an earth worm. It moves very slowly, without turning, and I could not decide at which end the head was, as it moved with equal facility in either direction. Great numbers of these forms could be seen in the field of the instrument at the same time, swimming with slow motion from side to side.

It is not pleasant to think that great quantities of this vile substance—useful only as a fertilizer—lie in our principal streets, and that it is blown about to be inhaled by ourselves and children. It finds its way into our houses, and when the carpet is swept or our clothes cleaned it rises in dusty particles to fill our lungs, and perhaps to deposit the germs of obscure diseases. It gets into the tanks on the house-tops, and we drink it in our tea and eat it in our food. May it not be that certain diseases which are charged to sewer gas have their origin in this cause?

EFFORTS are being made to open up the Yaqui country, Sonora, in which some big strikes have been recently made. Trouble is feared from the Indians.

ARRANGEMENTS have been made to have two or three hundred tons of ore from the Live Yankee mine, at Spring City, Nev., worked at the Bullion of Paradise mill.

THE bullion shipments through Wells, Fargo & Co.'s office in Nevada City last month amounted to $60,875.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

San Bernardino Mines.

Editors Press:—The Mining and Scientific Press still comes along to an old quartz miner, though I have not worked my mine as usual this season, hut took a flying trip to the mines of San Bernardino county, to Calico mountain. They are ahout 80 miles eaeterly from Colton, S. P. R. R., and 8 miles heyond the seoond crossing of the Mchave river, 20 miles up said river from old Camp Cady. The mountain lies on the same range as the Waterman mine. Some of the mines are in high grade ore, with chloride milling rock. There are about 100 people in the small town, which is on a little mesa betwcen the two gulchee or washes. There are spots or stringers of galena of no material value and worth only from $2 to $5 per ton.

The best locations are within a mile or two of the town, the Moecow and Oriental No. 1 and No. 2, the Mark Twain, Little Waterman and Nellie Gray. These mines may come out, but the wood question is undoubtedly chief. There is no water in the Mohave river, except for steam, it is so low down. Scattering cottonwood groves may be seen along the river, hut they will not last long if two 10-stamp mills are to he rnn. Most of the people there are not miners, but ranchmen. The Mohave river hills, for 50 miles above here, contain gold, silver snd copper deposits that will eventually he utilized when the California Southern is finished and a more intelligent and practicsl class of miners go there to operate, and do not ask so much as to drive off all men who have money and hrains. Then, evidently, other classee will rule.

There is one 10-stamp eilver mill running near the Calico mines with success. Forty miles up is the Los Angeles company, having a 10-stamp water-power gold mill, and employing Chinese miners. A brother of Governor Blaisdell is chief owner. The ores are pretty good. The country is alive with proepectors, who go out on the desert waetes aud sand plains to prospect, with huggies and huck-hoards and two-horse wagons to haul grub and water. In snmmer it is extremely hot and dangerons with abundance of water; and in winter it puts you in mind of the upper Missouri river and hleak plains.

There is but little wood to cook with, though the dry grease wood grows everywhere, and has to serve as firewood. The Indians are civil, but there ie no game here. It is a mineral country everywhere from the Colorado river to the Cajon pase. The are many valuable mines, no douht, heside the horate of lime and borax under the surface or the sinks and flats, chiefly cotton ball variety. I heard of some valuable lead or galena mines in my rambles from Sen Bernardino. The Mohave is no river except in winter floods. Not much of the land is adaptable to farming.

The sands hlow over what little good land there ie if the freshets do not cover it with sand. The climate has unpleasant extremes. The coarse graee is brittle and stiff in the marshes. Nothing can live on theee plains without hauling gruh, except land turtles or lizerds or an occasional jeck-rabhit. It is said that Calico will open up eome valuable mines, and they will go deep, Some of the ore has worked as high as $400 per ton, in Sen Franciaoo, by the carload. Yours,

S. D. Blade.

Snmner, Kern Co., Cal.

Damascus Steel.—Perheps one of the best methode which has ever been discovered for tempering eteel, resulting in hardness, toughness, and elasticity combined is that followed in hardening the blades of the famous Damascus sworde. The frnace in which the hlades were heated was conetructed with a horizontal slit by which a current of cold air from the outside entered. This slit wae always placed on the north side of the furnace, and was provided on the outside with a flat funnel-ehaped attachment hy which the wind was concentrated and condncted into the slit. The operation of tempering the blades wae only performed on those days of winter when a cold strong north wind prevailed. The sword-blade when bright red hot was lifted out of the fire and kept in front of thie slit and by this means was gradually cooled in the draft of air. It acquired the proper degree of temper at the single operation.

Bitter Root, Montana.—A correspondent of the Butte *Miner* says: Butte ie supposed to he the finest mining cemp in the United States, but ths Bitter Root mines will, inside of two yeare, he the richest of any mines in Montana, and even more. It must he remembered that only ten months ago the hoom started here, and, furthermore, we have the best timhered and watered country in the world. Wood is plenty anywhere within a quarter of a mile of any of the minee, and water the same and plenty of it. All kinds of building timber are plenty. Lumber is cheap—from $8 to $12 per 1,000 ft. There wae a large emigration here last year, which will be twenty times greater this year.

Salt Furnaces.

The salt manufacture and salt interest in Kanawha and Mason counties, and of West Virginia, have been written up by Dr. J. P. Hale, Charleston, in a pamphlet on the resources of West Virginia. In his article, which we have read with pleasure and profit, is an interesting account of the digging of the first salt well. And there ie also a description of the methods of transportation of, and those of manufacturing the salt. From what he says about the salt furnaces we take the following:

After the introduction of steam power, end the use of coal for fuel, no striking change was effected in the procees of salt maufacture for a number of years. What improvemente were made, were simply in degree. Wells were bored deeper, the holes were bored larger, the tubing wes better, the pumps and rigging simpler. The furnaces were larger, better constructed, and more effectively operated, the quality of the salt improved and the quantity increased, hut still they were kettle furnaces of the original type.

The mammoth of the kettle era was that of Joseph Friend & Son, at the mouth of Campbell's creek, on which they made 100,000 hushels of salt per annum. The usual capacity of other furneces was 25,000 to 50,000 hushels per annum.

This was about the condition of the salt manufacture in 1835, when there were, all told, about 40 furnaces, producing annually about 2,000,000 buehels of salt.

During this year Geo. H. Patrick, Esq., of Onondaiga, New York, introduced a patent steam furnace.

The furnace proper, after it was developed and improved, consisted of cast-iron pans, or hottoms, 8 to 10 ft. hy 3 ft. Eight or ten of these pieces were holted together hy iron screws, forming one section 24 to 30 ft. long, hy 8 or 10 ft. wide. There were 2, 3, or 4 of theee eections, according to the size of the furnace. Over each of the sections was constructed a wooden steam chest, holted to the flanges on the sides of the pans, and otherwise held togcther by wooden clamps and keys, and iron holts and rods, all made steam and water-tight by calking. These several sections are set longitudinally on the furnace wells to form one continuous furnace.

After the furnace comes a eeries of wooden vats or cieterns, a usual size for which ie ahout 10 ft. wide and 100 ft. long. The number of these cisterns varies according to the size of the furnace. They are conetructed of popla plank, 4 to 5 inches thick, dressed to joints, and fitted in a frame of oak hy sills and clamps. They are tightened hy driving wooden keys, and then calked to make them water-tight. Thie system of clamping and keying cisterns was introduced here from a model brought hy Col. B. H. Smith, from the navy yard at Norfolk. It was very simple and effective, and has been retained to thie day, without improvement or change.

There are two sets of these cisterns; the first in which the brines, after hoiling in the furnece proper, are settled, and at the same time strengthened up to saturation; the latter, in which the salt is graduated from the clear ssturated hrines. These settling and graining cisterns are very much alike, except that the grainers are but 15 to 18 inchee deep, while the settlers may he double tbat or more. Through each and all of these cisterns from end to end are three rows of copper pipes, usually 5 inches in diameter.

After the ealt water is hoiled in the furnace proper, it runs into these settling cisterne, and after being thoroughly settled and saturated, is drawn into the grainers, where the salt is deposited, and once in 24 bours is lifted out hy long-handled shovels, on to a salt hoard, suspended above the grainer, and from which, after proper draining, it is wheeled in wheelharrows to a ealt house, where it is packed in barrele ready for shipmeut. The steam geuerated by the hoiling in the furnace proper is carried from the steam chest, hy wooden pipes, to the copper pipes and through the settlers and grainers. This steam giving up its heat in passing throngh these cisterne, keeps up the temperature of the hrinee, and causes rapid evaporation. The temperature of these cieterns varies from 120° to 190°; an average would probably be 165°. This, in short, ie a description of the steam furnece, after it was improved, and the first mistakes and crudities eliminated. In the first experiments only very elight heat was imparted by the steam to the brinee, and only very coarse or alum-ealt made. It was very simple, accomplished all that was expected, and so soon as it was fairly teeted, improved up to its working condition, and its advantages demonstrated, the daye of kettle furnaces were numbered.

Andrew Donnally and Isaac Noyes were the firet to try and adopt the plan. Then followed John D. Lewie, Lewis Ruffner, Frederick Brooks, and others, till all had mede the change; and when the Ohio river furnaces were built, the system was fully adopted there.

It is now about 40 yeare eince George Patrick introduced the eteam furnace, but it still holds ite position securely, and without a rival.

Minor improvements have heen made and the furnacee much enlarged, but the general plan has not been ohanged. From the 2,000 or 3,000 or 4,000 buehels per month of the earlier furnaces, the production has been increased to 20,000, 30,000 or 40,000 bnshels per month. The writer'e furnace, Snow Hill, has made in one year, independent of all stoppages, delaye etc., 420,000 bushels, the largest single month's run being 41,000 bnshels. This furnace has 20,000 equere ft. of evaporating cistern surface, and over 1,300 square ft. of metal-pan furnace surface. About 1,200 bushels of coal per day are consumed in the furnace proper, and ahout 300 more for engines, houses, and other purposes.

In the earlier times of salt making here, various substances were experimented with for the purpose of settling or eepsrating the impurities from the hrine: Blood, glue, jelly, lime, alum, etc., were used. Something of the sort was necessary when the brine was hoiled down in kettlee with all its impurities, hut they are all useless, and worse than useless, in the preeent process, and have long been ahandoned. Plenty of eettle-room and plenty of time are all that are needed to have the brines as clear as spring water. The bitterns, after the salt is granulated, are thrown away, or used for other purposes.

It has long heen known that a small portion of some greasy or oily substance on the surface of the hrine helped "to cut the grain" and hasten the granulation. Butter, tallow, lard, rosin, oils, etc., have heen tried. Of these, hutter is far the best, and next to butter, tallow; lard and some of the others are positively detrimental.

What the action of hutter is, whether chemical or mechanical, or both, I thiuk has never been determined, hut certain it is that a very small quentity of hntter on the surface of hrine while it ie granulsting very much improves the salt, making the grain finer and more uniform.

Heat, too, is an important condition in making fine salt. The higher the temperature, other things heing equal, the finer the salt. In making the finer grades of table and dairy salt, it is necessary to have the hrine up to, or near, the hoiling point.

On the other hand, the coarser grades of salt, preferrred for meat packing and other purposes, are mede at temperatures of from 100 to 150 F.

A still coarser grained, or larger crystaled, selt, known as alum salt or solar ealt, and made in the open air hy solar evaporation, is not made here, hut there is no reason why it should not be to great advantage, as we have long summers and warmer suns than at Onondaigo, New York, where it is very largely made, and with more profit than other grades of salt.

The cost of msnufacturing ealt on Kenewha varies, of course, from time to time, with the varying price of living, lahor and supplies. It also varies with each particular furnace according to eize, and the greater or less advantages which it possesses. The larger the furnace, other things heing equal, the cheaper it will make salt. The general superintendence and management of a large furnace, costs very little, if any more than for a small one; and a given quantity of coal will make more salt on a lerge furnace than a small one.

The hest furnace will make 100 hushels of salt with 80 to 90 hushels of coal. A good average result is a huehel of salt for a hushel of coal, and the least economical consume ahout 125 hushels of coal per 100 hushele of salt.

Some of the furnaces mine their own coal, and some huy fine or nut coal from mines that are shipping coal. Even the hest furneces do not use coal at all economically or to the hest advantage. There ie, in this respect, great room for improvement.

The coet of coal delivered at the furnaces, ranges from 2¾ to 4 cents per hushel. The present cost of barrels is 25 to 28 cents for the smaller size and 28 to 32 cents for the larger. The cost of common day labor is $1 to $1.25 per day. Coal miners get 2 cents per hushel.

The cost of producing salt at these figuree may he stated at 8 to 11 cents per hushel in hulk, or 13 to 16 cents in barrele, ready for shipment.

The present cost of horing a salt well here, say 1,000 ft., after engine, well frame, etc., are ready, is $1,200 to $1,500. The time necessary to hore and ream it complete, is 60 to 90 days. The cost of a salt furnace complete, depends upon size, etc., and variee within wide limits. It may he stated roughly at $40,000 to $100,000.

Prospecting for Water.

The Uses for which the Diamond Drill is Adapted.

The diamond drill is now one of the best and most useful toole used in our mines. All Pacific coasters will remember the howl that was raised when the diamond drill wee first taken iuto the lower levels of the Comstock. Indeed, such a row was kicked up ahout it, that the drill was secretly taken into minee and was run on the sly. In thoee days the miners themselvee (for reasons of their own) were not very friendly to the diamond drill. It was then thought to he a great thing for nse in finding out ore hodies; hut it was not long before not a few discovered to their cost that for such use the drill was very unreliable.

The great use of the diamond drill, says the Virginia *Enterprise*, is now acknowledged to be not in hunting for ore, but in guarding against water. When the drill has heen rnn ahead and the ground to he passed through probed for a dietance of 150 to 250 ft., the miners feel perfectly eafe in banging right along on a drift.

In most of our leading mines, euch great depth has been attained that it is very dangeroue to pueh into unexplored ground with a drift. Bodies of water are liable to be reached that etand under such pressure that the whole face of a drift may he forced in and a torrent of scalding water poured out. In the event of suoh an accident occurring, the men could only rnn for their lives to the nearest shaft or winze. In not a few situations, loss of life would be almost inevitable. Suppose, for instance, that the men drifting on the 2700 level of the Ophir or Mexican shonld tap a flood of water, what would become of the men at the bottom of the winze on the 2900 level? The men out on the 2900 level would he scalded to death—cooked by the hot water and the steam—almost as soon as the flood hegan to tumble down into the winze.

But for the fact thet they know that the ground into which drifts and crosscuts are heing thundered with huge blasts of Giant powder have heen thoroughly probed with the diamond drill, there are many places in all our mines into which it would he almost impossihle to indnce minere to go. When a man has descended a winze 200 or 300 ft., then has moved out in a drift from the hottom of said winze 500 to 700 ft., it is not pleasant for him to think that, by a blunder made on a level ahove, a small river of scalding water may suddenly he seen pouring down and cutting off his only means of escape.

It would he impossible to get along in our mines at the present denth without the diamond drill, as all mining men know. Miners know this as well as do euperintendente, and feel just as friendly toward the diamond drill, once such a bughear, and by so many conceidered a swindling tool invented hy either Jim Fair or the devil.

Women's Shoes.—Take the most recent fashion of shoes. The heel of the hnman heing projecte outward, or rather hackward, and gives steadinees to "the sure and certain step of man." But fashion has decided that the heel of the hoot or shoe shall get as near the center of the instep as possihle. Instead of the weight resting upon an arch, in the modern fine ledy it rests upon pegs with the toes in front which have to prevent the hody from toppling forward. Then the heel is eo high that the foot rests upon the peg and the toes; and the gait is ahout as elegant ae if the lady were practicing walking npon etilts. In order to poise the body on these two points a bend forward is necessitated, which is regarded as the correct attitude of the "form divine." It is needless to say that there are few ankles which can stand this strain without yielding; and it is quite common to see young ladiee walking along with their ankles twisting all ways, or perhaps with the sole of their shoe or boot escaping from under the foot and the side of the heel in contaot with the ground. With such modern improvements on sandals (which allow the feet perfect freedom and play) the present msdemoiselle, when she attempts to run, ie a spectacle at which the gods—well, not quite that, hut at which her mother might well weep.—*Good Words.*

Important Mining Decision.—Tbe important mining decieion rendered by Justice Miller in the Circuit Court of Colorado, which was recently referred to as having nearly reached the point of finel review hy the United States Supreme Court, is to the effect that no mineral land patent can legally issue for more than 160 acres, and that if a nnmber of original locations have heen consolidated into one claim, each of the locations must be treated as a distinct claim, and advertised and proved up with proof of separato work upon it. This decieion, if sustained by the Supreme Court, would, it is said, destroy two-thirds of the patents heretofore iseued for mining claims, and make the procuring of patents for most of the old claims impossihle, hecause of the impracticahility of making proof of old locations, snd because in most instances eeparate work hae not been done on the old locations, which have been consolidated into larger cleims. Thus a shaft sunk on a consolidated claim has heen held to he work done in every part of it, but the Circuit Court judgment overthrows that principle. The appealed case hae been twice argned in the Supreme Conrt, and its forthcoming decision is awaited with great interest.

Discovery of a Nickel Mine.—A. J. Malthy, of White River, claims to have discovered a nickel mine. Ho etates that the croppings show a good percentage of the metal, hut ae yet he has taken no eteps to determine the extent or value of the find. This metal has very usefnl qualities and would be valuable if found in larger quantities, but the scanty eupply has restricted its use and the demand for it ie limited, through thie cause alone. It occupies no prominent place as an article of commerce, and we do not know that it has any fixed velue like other metals. A mine of it is worked in Lancaster county, Pennsylvania, which furnishes the Government with what is used in the coinage.—*Kern County Californian.*

More Valuable Than Eastern Papers.—The Mining and Scientific Press should find a place in every miner'e home. It conteins much practical home imformation and as a matter of fact is far more interesting and valuable to Pacific coast people than any Eastern pnblication. Dewey & Co. of S. F., are doing mnch toward the development of our varioue resources throngh their untiring efforts.—*Georgetown (El Dorado county) Gazette.*

A new hydraulic ship has heen tried in Germany, and succeeded in making nine knots an hour. She is driven by forcing water ont of tubes with narrow outlets placed in the stern.

MECHANICAL PROGRESS.

Solidity in Machinery.

The treatment of iron in machinos has, for many yeare, heen too mnch like its use for toys and ornaments, a pretense of lightness in imitation of other material. The eaving in the first cnst of oastings, and in the price of wrought iron has hecn a large, if not a principal element in the prodnction of all machincry prodncts of iron. Lightness of material and airy elegance of form have heen frequently qnoted as evidences of superiority. Lote of this sham trash have fonnd their deserved way to the scrap heap snd the foundry cupola, hut muoh more remains tn he relegated to the same deetination.

The trifling with the capahilities of cast iron seen in common architectural ornaments and lawn and cemetery fences can he horne, as it is merely an offence to common sense and good taete; hut the tricks shown hy economic builders nf machinery, especially machine tools, are reprehensihle.

I know of an inetanoe where a maker of nrdinary household pumps, of cast iron, deliberately threw aside an entire set of patterne, hecauee hy a new eet (costing more) he could save 20 cents on the cost of weight of castings for each pump. He probably lost on the price of the new patterns, on the haulks in the foundry hy thinnor patterns, on the after work oy having harder iron, and on the additional grnmhle by purchasers of the "improved" pump, which they returned hroken, a mnch larger amount than the supposed cheapening of the pnmp hy the saving of iron. And yet thie lightening the weight and decreasing the cost of the iron castinge is to-day a considered element in machine huilding; and the manufacturer who csn show the lightest csstings—other requirements heing eqnal—is the one who helieves himself to have arrived the nearest to mechanical perfection. These irnn savers seem to imagine that iron ranks among the preoious metale, and ie valned solely by its weight, and hardly hy its uefulness. Or, they seeume to he æsthetic in ite use, and desire to he recognized hy their artistic taste in forming it.

All this is nonsense. Iron is not adapted to worke of art, the cast iron ststnes of modern times and the wonderfnl forgings of mediæval times to the contrary notwithstanding. There have heen surprising achievemente in the fashioning of iron hy hand, and remarkahle results from the molten metal; hut none of them prove the proper spplication of the metal to be that of furnishing tasteful forms or artistic products.

In the mechanic arts iron is a resistsnt. It occnpies in mechanics a place eimilar to that of grsnite in architecture; it is to resiet, and bear, and suetain, and hold. In fact it is shown at its best in the anvil, and this idea should be the prevalent one in the building of macbines, especially those that are worked hy reciprocating motion. It is of lese importance that rotary working machines should he unusually stiff, as the strain is mostly continuous.

Bnt the planer and the header (of rivets and screws) test the capacity of iron. Think of a planer platen with a load of five tons or more—in many cases double that amount—moving in one horizontal direction at the rate of 20 ft. per minute, brought to a sudden etop, and started on a reverse, or return, speed of 30 ft. per minnte; what sort of material, but iron, could stand snch shocke, repeated over and over, day by day, for yeare? And yet one may etand by the heade of planere and with the finger feel the "give" as the chip "takee," and as for the shock of the retnrn, the entire floor responds to it.

It is quite evident that exact work is impossible under euch circumstances. One fault with many of onr planere is that the nprights and the crose-har are not etrong enough; they have not iron enough; they give to every chip-take. So little is thie matter considered that in one shop recently visited one planer had its uprights of solid weh and gradually curved in a oonvex radiue from the top to the hed, while one other, of the same size, had a weh with three great holes in it and the hackward curve made into a section of an ogee molding. Yet both of theee planers were used for similar work.

It ie difficult to make tests of the failure of weak machine tools in operation, owing to the general tremuloneeee of the shop; but the writer has heen aceured, by one who hae tried to aecertain the differences in machines in actual work, that he has made eatisfactory experiments to the effect that the upper part of the uprights of a 40-inch planer "winked" three-sixteenthe of an inch on taking the chip. Possibly part of thie was due to insecure foundation, ae the the planere tested were on a second, or supported etory.

But there is another lack of solidity in the burden-bearing quality of machine tools. It may be a matter of doubt if the beds of planers loaded with a job are usually level, or etraight. If eome recent diecoveries made hy a prominent machine tool builder are true, tbe really level planer bed is the exception. Failing in getting good resulte from his heaviest planer, which freqnently planed a load of nearly six tons, he instituted experiments that indnced bim to build a pier of masonry under the center of his big planer, from the hard pan of the cellar, and mount on it two jack-screws, one nnder each planer "way," to keep the plsner from sagging while at work. He stated that the sag in the length of 10 ft. wae "more than one-eighth of an inch." It ie eoarcely to be doubted that this experience could he duplioated in many shops.

If such discrepancies exiet in general shops, similar ones may he possihle in others where tools of procision are produced. If exactness ie desirahle in mechanical work, it should hegin at the heginning. First let the tools—the machine tools—have plonty of material, and then place them on secure foundations. This present plan of hnilding storied buildings, and raising addednl additinns above the ground, mnst he given up before tools of precision can he produced with aheolute certainty. And our tool builders and machine manufacturers must cease to look upon iron as a costly material, but regard it as a convenient means to a desirahle end. —*Cor. Boston Jour. of Com.*

FRICTION MACHINERY.—The operation of friction machinery has now become a fixed fact, and its eaey adaptability where waste power can he utilizsd is a marked feature. A machine of this kind has come into use, which consists simply of an iron cylinder one foot long and one foot in diameter, having a fixed plate of hardened iron in one end, and a second plate attached to a revolving shaft, which presese lightly or closely upon the fixed plate, as circumstances require. The cylinder is filled with water, the ehsit revolves, and from the friction of the plates, the water in an incredibly ehort time is heated, and hy means of steam pipes can he carried to great distances for heating purposee. The machine is so constructed as to render it easily adapted to all places where there ie waste power, as in mills, factories, puhlic huildings, cars, etc. The power required for its operation is very slight; thus, to carry a machine with thirty-six equare inches of friction plates—the ordinary size—one horse power only is reqnired, while a machine with two hundred and twenty-five square inches of friction surface will require at most but six horse power.

EFFECTS OF COLD ON STEEL.—Observations made eome time eince on Russian railways ehow the effects of cold on steel. From figures pnhlished it ie learned that from Oct. 1, 1879, to March 31, 1880, 480 fractures of tires (18.9%) occurred while the temperature wae ahove zero, 105 frsctures, or 4.1%, at zero, and 1,952 fractnree, or 77%, at temperatures helow zero. The greatest nnmher of fractures happened on Dec. 9th, 10th, 17th and 23d, 1879. The ahove interesting data prove that the frequency of fractures during the period etated must be attrihuted to its ahnormal atmospheric conditions. Of the fractures recorded, 3,269 occurred in ingot steel tires (crucible, Bessemer, Martin and manganese steel) and 1,045 in tires of puddled steel or wrought iron. Tires of fine-grained iron and puddled steel appear to he safer, while ingot steel offers greater advantages ae to wearing. The thickness of tires also playe an important part in their resistance to the effects of cold, the greater nnmher of fractures occurring in thoee of smaller thicknesses.

A NEW MACHINE WANTED.—A Louieiana sugar planter writes to the *American Manufacturer* that there is great need in the South for a machine that will crush or grind unshncked ears of corn, as they come from the field, into a coarse meal of corn, cob and husks, and do it rapidly. He ie aware that there is a machine that will crush corn in the ear thoroughly, one ear at a time; what be wants is something that will receive a hushel of eare or nuhbine at once, and crush, say, 20 hushele an hour. One of the great trouhles of eugar planters, he says, is the preparation of food for their mules. To crush corn in the ear with exieting appliances, the corn has to he husked, coeting much labor, and tbere is apt to he a great loee of small ears. "A fortune awaits the inventor of a machine to crush hy the wholesale corn, cob and shucks together." The problem does not seem to he a difficult one, and eome of our inventive readers may find it profitahle to nndertake the solution.

MANUFACTURE OF CELLULOSE FROM WOOD.—Dr. Richard Mitscherlich, in Darmstadt, emploge the following process: Reducing hodies diseolved in water and acid, preferahly sulphate of lime, are heated for eome time with wood under great pressure. The wood remains a fihrous mass, while the bodies which produce its disintegration are eaeily removed. The wood fiber, of which generally more than nine-tenths of the wood ueed is ohtained, is treated after the chemical process by a mechanical process, and can afterwards be used for the manufacture of paper, raw tissues, etc. If bark, straw, flax, etc., is used instead of wood, a finer fiher ie ohtained by this process than it was formerly poesible to obtain with the eame materials.

TIN PLATE MANUFACTURE.—The term "char coal" on tin platee ie a fraud and alwaye was. None but coke irons have ever been need in the manufacture of tin plate. In fact tbe most ductile irons made in England or on the Continent of Europe are smelted with coke. This country produces brande of iron better adapted to making tin than any in the world. Our heat West Tennessee and Alahama irons are as much euperior to British brands for tin plate as they are for boiler iron or car wheels.—*Chattanooga Tradesman.*

SCIENTIFIC PROGRESS.

Electricity as a Motive Power.

The *Manufacturer and Builder* says that the development of electricity as a motive power is an aim which, though difficult of realization, is yet so strongly to he desired. Its achievement is not very far off, if we may take the utterances of some of the hest authorities on the subject as couclusive evidence of the probahilities of the future. For example, M. Bontonx, presiding recently at a meeting of the Parisian Society for the Utilization of Electric Force, observed that the artisan who needs a little motive power for his work, ie forced to seek it in the employer's factory, while thousande of workmen and workwomen wear out their hodies and destroy their strength in impelling the sewing machine, the lathe, and other motive powers of small industry. The division of electrio energy is destined to effect an entire revolution in this sphere.

The day will come, and sooner than is imagined, when the srtiean family will see enter their dwelling hy means of a magic wire, the force which is now so costly to them, and this will he the democratization of force for the benefit of the working class. The solution of the question of motive force in mechanical indnetries is, by this, apparently not far distant, and it ie curious to contemplate the changee in our social and puhlio arrangements which euch a development of tbe electric motor would accomplish. If an efficient, actuating agent for small machines of every kind could he resdily obtained and cheaply purchased, what a revolution would come over the exieting lahor market! How many work-shops for men and work-rooms for women would be closed, and quondom employeee supplied in their own homes with the means of carrying on their work in their own apartments. Without attempting to forshadow all that might happen, certain it ie that the coet of driving lathes, and machinee of every kind, would he largely diminished, and the means and motive for extending their application eupplied.

From all points of view, it ie much to be wiehed that this novel mode of actuating machinery may he developed so that its efficiency and economy may estahlieh a reputation, and be largely patronized hy hoth large and small employers of labor.

Electric Reservoirs.

In counection witb the ahove the following from a late numher of the London *Times* will also he of special interest:

Some interesting and succeseful experiments in the suhdivision of the electric current were shown on Monday afternoon to a party of gentlemen who visited the works of Mr. Rogers, of Farrington street. Mr. Rogers claime for his invention that it will enahle him to supply electricity for domestic purpoees as water and gas are now supplied; and that from a cistern or reservoir, to which the current must he conducted hy the main wire, and which may he carried to every room in a houee. The novelty of the eystem, for other methods of suhdivision exiet, lies in the ease and completeness with which the current is distrihuted over the wires, and in the fact that it is rendered almost infinitely divisible without much loss of power.

A town cannot be supplied with water hy a mere ramification of pipes, and, following the idea, the inventor of the system we are sketching, whenever he desires to suhdivide the current of any given wire, collects it in a small cistern or reeervoir, from which it ieeues again through ae many wires as it may be neceseary to attach. Thus, in lighting a large huildiug hy electricity, the main wire would convey the current to the chief cietern on the ground-floor or in the basement, wbence it would be distributed among subsidiary cisterns, of which there would he one or more on each floor of the house, and these in turn would transmit the divided current to each separate room.

The experimente made on Monday demonstrated the efficient action of the cisterns or reservoirs, on which the success of the whole eyetem depende, and ehowed that tbe current of a single pair of wiree could he made to supply an indefinite numher of lamps. Edison lamps were ueed and received the current from eix cisterns, the suhdivision heing such that it mattered not whether each cietern supplied one lamp or half a dozen. This, it must be admitted, is one method, and not an unsatisfactory one, of solving a problem that has long vexed practical electricians. An ingenious modification was aleo ehown of the apparatus known as Barker's mill for driving a dynamo-machine hy water power, with a governor so contrived as to eneure the application of an unvarying degree of force, and by consequence a perfectly even and unfluctuating electric current.

MECHANICAL EQUIVALENT OF HEAT.—It does not appear to he generally known that the value of the mechanical equivalent of heat has within a few yeare been corrected. It is generally referred to hy mechanical writers at 772 foot pounds. Dr. Joule repeated his famous experiments in 1876, nearly six years ago, with extraordinary precautions, and the mean result of 60 experiments gave 774.1 foot pounde, with a possihle error of 1-400, on account of the "thermometric scale error." This value shonld he used in all calculatione relating to the value of heat as a motive power.

Are Metals Volatile?

Quite different views are held hy chemists snd practical smelters, snd the question implies a waste or ssving of ahout 10% of all the gold and silver smelted every year, amountiog to $50,000,000, thus an actual lose to the country of $5,000,000 annually hy a needless waste, if metals are vaporous or hecome so under certain oonditions of heat or chemical reactions, as held hy Dr. Duryee.

Iron is entirely non-volatile, while the phosphorus in it ie volatile if chlorine and sufficient heat be applied.

Lead is vaporized at a red heat; zinc ahout the same. The telluride of gold ores is found to he impoesihle of smelting in ordinary cupola furnaces, hecause tellurium gives to gold the property of hecoming volatile at a red heat, while gold itself is considered non-volatile at even a white heat; but it is found chlorine has the property of combining in a gaseous state with gnld at a heat of 4,000°, rendering it so volatile that its vapors can be ssrried into a proper condenser and there condensed the same as oil vapors are condeneed.

It is found hy furnacemen that silver and lead when smelted together are carried off to the extent of 10% to 30%, even at ordinary furnace heat, and it is hecoming a serious question around Leadville how to overcome the effect of lead poieoning from the numerous furnacee.

By several analyses of Duryee's furnace slage from gold and silver oree, it was found that the metals were all vaporized down to 10 or 50 cents per ton of ore, and as it is extremely easy and simple to condense these vapors, this mode of working the precious metsls would eeem to he the surest business sagacity on the part of smelting or mining companies.

It now having been shown that all metals are vaporous, or can he made so, it is only a question of time when all the vapore will he saved. Who knows but that the distilling of metals will he as esey as distilling oile or cider! Any oxy-hydrogen hlow-pipe heat on a large scalo properly applied would seem to us feasihle and practicsl. —*Hall's Journal, December.*

ELECTRICITY FROM CRYSTALS.—It has heen sbown that, hy the mere compression of an inclined hemihedral crystal, electricity is developed. Experiments were made hy placing a crystal, or a suitahle section of it, between two sheets of tinfoil, insulated on the exterior hy platee of caoutchonc, the tinfoil being connected with a galvanometer. By compreseing the crystal into a vise or otherwiee, electricity wse developed and measured hy the galvanometer. The electricity developed is the opposite of that produced hy heating a crystal; that ie to say, the extremity of the crystal which hecomes positive on heating, hecomes negative on compression. On releasing the pressure, electricity of an opposite kind is produced. It was also found that the electricity by preseure can only he ohtained from hemihedral crystals having inclined faces. By combining a number of inclined crystals in a pile, an apparatus for producing electricity has been invented. The amount of electricity developed varies for different materials, a section of quartz, cut perpendicular to the main axis, evolving more than a similar section of tourmaline.

SELENIUM AS A HEAT REGULATOR.—The sensitiveness of eelenium to radiation ie to he made use of in regulating the heat of muffle furnacee. The concentration of rays, more or less, upon selenium, influences the electric conductivity of the material, as most people know, in a marked degree, and this property M. Germain proposes to make use of to control the heating of furnacee. A window in the furnace, made of very refractive alumina glass, permite the red glow to reach a dietant mirror; the rays are reflected upon selenium, and when the light reaches a certain stage of hrightness the electric actiou of the selenium conductor is snch that it acte on a mechanical arrangement by which the fire-hare of tbe furnace are withdrawn. The fuel of the furnace is thus allowed to fall out as eoon as the right temperature for fusing enamels hae heen reacbed. The *Photographic News* saye: If a self-acting selenium actinometer of this kind will permit the firing of enamels with certainty, pbotographers will not be slow to avail themselves of it.

PRESSURE OF GAS IN COAL.—Mr. Lindsay Wood has reprinted a paper which he read hefore tbe Newcastle Institute of Mining Engineere, "Experimeuts on the Pressure of Gas in the Solid Coal." These experiments are made with great care by boring into the solid coal to a considerable depth, fitting in a pipe, and connecting it with a preseure gauge. At Eppleton mine, at the depth of 1,261 ft. from the surface, the preesure reached was 104½ lbs. per square inch. At Boldon one experiment gave 386 lbs., and another 461 lbs. These enormous pressures sufficiently indicate the canses of many of our colliery explosione, and convincingly estahlisb the neceseity of adopting some method by which the gas may be drained from the fiery coal seame.

FINE DRILLING.—Prof. Edward C. Pickering, of Harvard College, eays tbat, in undertaking to measure the intensity of the light of the catellitee of Mare, he had occasion to need an extremely small hole. A hole about the *twenty-five-hundredth* part of an inch in diameter was finally secured.

THE miners about Silver City have got out more ore than the little water-mills along Gold canyon can work. The mills got behind during the cold weather, when their wheels were all frozen up. Some men with small lots of ore have been waiting a month or two to get them worked. A few are now hauling their ore to the Merrimac mill on Carson river.

BIG PINE is at present somewhat despondent. The Montezuma mine has suspended operations. Various reports are in circulation as to the cause; there is one truth, the mine has "shut down." Bishop had her Poleta, Big Pine her Montezums. The result is contrary to all public expectations.

THE New York *Stock Report* says: The sum of $2,990,653,03 in gold and silver has been received in this city from the mines since January 1st.

THE hullion shipments from the Horn Silver during February amounted to 2,889,239 lbs.

NEW MEXICO bids fair to be second only to Michigan in the production of copper.

The Mining Share Market.

A fair amount of business has been transacted during the week, but with no marked advances in prices. Upon the Comstock the water question is still prominent. The *Enterprise* says:

Although at the Gold Hill mines the "fountains of the great deep have been broken up," and the waters have "prevented exceedingly," yet Capt. Taylor, the Noah of the Yellow Jacket ark, says the dove now comes in to him with an olive leaf. In the last five days the water has risen hut 17 ft., and hut 18 inches in the last 24 hours. This shows that the water has about found its level. As five strokes per minute were required to keep the mine clear of water previous to the influx from the Exchequer, it is evident that the flow of water from that sonrce is now very light. Running at five strokes the pumps throw out 500 gallons per minute, hut hy increasing the speed to seven strokes (which is perfectly safe), and rnnning the hailing tanks, 1,500 gallons may he thrown ont every minute. From this it is evident that should a determined attack he made on the water it wonld he rapidly lowered. The present deluge is no worse than the last. That was "essnaged" in an astonishingly short time, and under many disadvantages not likely to he encountered on this occasion.

All that is reqnired is a little pluck and prompt action to rescne this grand old mine (now the deepest on the lode and the deepest in the United States) and place it where it helongs in the list of the Comstock mining properties. It is to the interest of all on the Pacific coast to do this. It will not do to desert the first mine that has attained the good rounds depth of 3,000 ft.

The Yellow Jacket company does not owe a cent. Let the present assessment he paid and it will not only pay all of the expenses of the present month, hut will leave in the treasury the ronnd sum of $100,000. This sum, with snch luck as the company have a right to expect, will drain the mine and allow of a resumption of work in the promising sections of the 2828 and 3000 levels, from which they were driven by the flood. And, let it not he forgotten, draining this mine drains all that are now water-logged—and the ark rests on Ararat.

ACCORDING to the report of Prof. Newberry, the Stewart mine, Bingham, has $5,000,000 gold ore in sight. Recent explorations make the estimate much larger, and it is thought with improved machinery this ore can he worked for $1 per ton.

RICH strikes in the districts southeast of Walker lake are continually reported. Garfield has been ahead lately.

AT Black Hills, recently, a run of 1,000 tons was made at the Grand Junction mill, the total cost of mining, milling, and placing retort in bank amounted to 80 cents per ton.

Bullion Shipments.

We qnote shipments since onr last, and shall he pleased to receive further reports:

Hanauer, March 9th, $4,250; Frisco, 11th, $5,955; Hanauer, 11th, $4,250; Leonore, 11th, $2,260; Richmond Con., 11th, $11,535; Alice, 9th, $7,000; Northern Belle, 11th, $7,350; Contention Con., 9th, $14,926; Diahlo, 7th, $6,705; Eureka Con., 2d and 5th, $19,686, Star, 3d, 1,306; Christy, 16th, $6,890; Eureka Con., 9th, $4,230; Northern Belle, 9th, $7,975; Father de Smet, 6th, $25,000; Bodie Con., 13th, $7,480; Star, 10th, $2,171; Mt. Diablo, 11th, $14,754; Contention Con., 13th, $17,256; Standard Con., 14th, $20,210; Bodie Tunnel, 14th, $2,250; Contention Con. (for Feb.), $128,000; Girard (for Feb.), $20.000; Grand Central (for Feb.), $110,000; Tombstone (for Feb.), $115,000; Vizina Con. (for Feb.), $45,000.

DEMAND FOR AMERICAN GOLD.—The European demand for American gold continues. This demand has been in operation for six weeks. It was prompted by the financial tronhles in Paris, and the consequent advance in rates for money at all the leading centers of finance. On the 2d of March the *Servia* took out $750,000 in double eagles and on the 4th the *Baltic* took ont $1,500,000, hesides $197,000 in fine silver. There were also two smaller shipments to the West Indies and France. The exports of gold from New York for the past five weeks amounted to $10,255,700 against $306,200 imports. It was expected that returning ease at London, Paris and Berlin, and a renewed activity in produce exports at New York would have checked this ontward flow of gold before now. But there must he elements at work which do not appear on the surface.

NEW SUPERINTENDENT.—Chas. Waldeyer, for a long time Superintendent of the Spring Valley mine, Cherokee Flat, Butte county, resigned his position this month. Mr. Waldeyer is well known in this State for his connection with the gravel-mining interests. He was a contrihutor on the subject to the U. S. Mining Commissioner's reports. Mr. G. F. Williams, who so successfnlly engineered the new tunnel, which we described and illnstrated in the PRESS of Dec. 31st last, has been appointed Superintendent of the mine. Mr. Williams, though a yonng man, has shown marked ability in his profession, and the appointment is eminently a proper one. He will now have an opportunity of exercising the executive ability of which he is known to be possessed. He is the son of Col. A. F. Williams, of Oakland, a well-known mining man, and who last season managed a prospecting expedition in Alaska.

CAPITALISTS are said to he flocking into Sonora. Throughont the State, new mining developments are being constantly made, and extensive preparations for the opening of old mines are engaging the attention of mining men.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

GOVER.—Amador *Ledger*, March 11: They are hoisting water at the Gover mine, with a view to commence working the mine. Hughes & Maxwell found 2 nuggets a few days ago, one weighing $20 and the other $19. They have changed their hase of operations to Mill gulch.

PLYMOUTH.—Madam Rumor has it that an almost unlimited deposit of gold was found in the Pacific mine last week. It is said that pieces of almost pure gold weighing $20,000 were taken out. I am unable to say whether it is true or not, but know that it is no better luck than Hayward usually meets with in new enterprises.

FROM VOLCANO.—The Downs M. Co. has just cleaned up, it being one of the largest ever made, amounting from $15,000 to $20,000.

MILL.—Amador *Dispatch*, March 11: Mr. A. M. Vaughn, the champion mill builder, has returned to town, he having just completed another 5-stamp battery for the Church Union mine, and we understand from him that the hoisting works of the above-named mine are going to he run by water power. One of Mr. Knight's improved wheels is to he used for the purpose. He also informs us that everything around the said mine, under the able management of Mr. L. R. Poundstone, is working to the perfect satisfaction of all parties concerned.

JUDGE REAVES has got his arastra to work, and is now putting through the auriferous at the rate of 3 tons in 24 hours, and, we understand, the prospects are of the most flattering character.

ETNA.—We have heard to-day that the Etna is yielding in a most magnificent manner, and there is no doubt but the enterprising parties now having the mine in charge will he duly recompensed for all the outlay they have made in opening this mine and putting in the necessary machinery to work it. Your correspondent has had a residence of nearly 33 years in the mines of California, and helped to make a sinking of 100 ft in this mine some years ago, and from north to south, and east to west, have never seen anything that looks like this deposit. The sulphurets lie in a heavy mass, in size from a pin-head to the size of a hen's egg, and seems to be embedded in a thin black muck or slum, and, at the bottom of the sinking we helped to make, it seemed that there was no limit to it, and free gold was visible sticking to almost every sulphuret, either small or large, that you might pick up. This vein is traceable for the distance of many miles between the Middle and South forks of the Cosumnes river, and, in fact, until it is hidden from view by the everlasting lava and cobblestone deposits.

PROSPECTING.—A good deal of active prospecting is going on, both north and south, and it is not all assessment work, for some of it is of a most permanent character, and we expect ere long to be able to chronicle some remarkable discoveries.

ITEMS.—It is reported upon the reliable authority that the California Bank intends at an early day to commence operations upon the Alpine.....Mr. Green Aden, who owns the land and mining property next, south, from the Pacific, informed us a few days ago that he was negotiating a sale of his mining property to a company from New York, and that he would receive every cent he had asked for it. Mr. Aden is one of those miners that do not believe in bonding mines.....Irish Hill is supplied with an abundance of water, and Mr. Phillips, the accommodating ditch agent, tells us that the prospects for the year's run were never better.....Whilst we hear very flattering accounts from Forest Home and Michigan Bar, and balancing everything, the cold and severe weather, the high price of hay, etc., I do not think there is any great cause for growling in this part of the county, unless it is with the patrons of the Plymouth school district.....It is expected that with the opening of the spring a new impetus will he given to mining in this part of the county, as we know from our own personal knowledge of a good many "bonded" claims that will be forced, under the contracts of the bonds, to commence work at a very early day, or else forfeit their bonds.

BUTTE.

BUTTE CREEK.—*Record*, March 11: In an interview with Pres. Longley a reporter learned that the Whisky Flat claim is now idle, work having been suspended while a new flume was being built, about 300 yards of the old one having been washed away by a recent freshet. The claim is located on Butte creek, about 2 miles above Helltown. It is a good claim, and has paid its owners well for their labor.

COLE CLAIM.—One of the best mines in that section of the county is the Cole claim, near Centerville, which has recently been purchased by a company of San Francisco capitalists. This claim has paid well from the start, and about $200,000 worth of gold was taken from it not long ago. The owners now have 25 men employed, and will shortly double the number. The latest improved machinery is used, and only experienced workmen are employed. A tunnel 2,000 ft long, with an opening of about 6 ft in diameter, has recently been completed in this mine. After the tunnel, entering so far into the heart of the mountain, had been completed, it was impossible for the workmen to enter it on account of foul air. Machinery was then purchased, and a shaft was bored from the top until it tapped the tunnel, which admitted plenty of fresh air. The shaft had to be sunk through a lava formation, and required a long time to complete it. But the fortunes of the owners are now assured. Three cars are kept constantly at work hauling dirt from the tunnel.

THE HART MINE—This well known and valuable claim is situated near Centerville, on the east side of Butte creek, and is in the Lava mountain. Mr. Crow, the superintendent, is an experienced miner, and is working this claim with flattering results. They now have a tunnel extended over 230 ft into the mountain, and have come across plenty of rich gravel, and a bonanza seems almost in the grasp of the owners. The tunnel was made in about 2 months, and will he pushed farther into the hill. Mr. Longley says that there is a stratum of goldbearing gravel in this claim, lying between the lava and the bedrock. This sort of gravel makes the heart of the old miner leap high. It is rich with the precious yellow metal, and does not require much labor to handle it. The gravel in question runs in depth from an inch to 10 ft. It has cleaned up $300 to a carload, holding about 5 wheelbarrow loads to a car.

CALAVERAS.

MONARCH.—*Mountain Echo*, March 7: It is said that work will soon be resumed on the Monarch mine, which has been lying idle for some time.

BOVEE.—Work has temporarily suspended on the Bovee mine, but will be resumed as soon as the weather settles.

CRUSHING.—The Matson Bros. have just commenced crushing ore from Fred Brunner's mine, near Albany Flat. This mine has never been thoroughly tried, but from what prospecting has been done on it, it is supposed to he a paying mine.

THE Rasberry mine, on the old Smith's Flat lead, is now being worked by a man named Patch. He is running an open cut into the hill for the purpose of giving the mine a thorough prospecting. This mine was discovered about the year 1855 or 1856 by Benega Rasberry, of this town, who, it is said, made a good deal of money out of it.

THE Dolan mine, the sale of which to Drake & Co., of San Francisco, was mentioned in a previous issue, is paying well, and never presented a finer appearance than at the present time. It is thought that the new company, upon taking charge of the mine, will erect a 60-stamp mill. There is, perhaps, no other mine in the State where the ore can he obtained at so small an outlay.

CAVED ON.—Calaveras *Chronicle*, March 11: Thursday last Mr. C. L. F. Brown, one of the proprietors of the Green

Mountain claim, on Tunnel ridge, about 1½ miles from this place, had a very narrow escape from death by being caved on. It seems that they are running a new tunnel, having abandoned their old one some months ago on account of the dangerous character of the ground, it being almost impossible to timber it so as to keep it from caving. Mr. Brown was working alone in the tunnel when, without any warning, the cave occurred, catching him about the head and breast, but luckily breaking no bones. With some difficulty he extricated himself from his perilous position, and managed to reach the "month" of the tunnel, where assistance was procured.

EL DORADO.

ENLARGING.—Georgetown *Gazette*, March 10: The Caf. W. & M. Co. is now engaged in enlarging its big reservoir just north of town. They are using a pipe and nozzle, which is being run day and night. The capacity of the reservoir is to be increased some 10 ft in depth.

TUNNEL.—Henry Jones, lessee of the old Marion England seam mine, is running a tunnel which will tap the quartz seams some 200 ft in depth. Henry is an experienced and drive-a-head miner, and is deserving of finding a bonanza.

GREENWOOD.—We have reason to believe that Greenwood district will be among the foremost this coming season in mining activity and bullion yield. In addition to the Argonaut, we have it from reliable source that two more important mines will shortly be fitted up in good shape.

STRIKE.—A rich strike was made yesterday in the Rich Gulch mine, just south of town, by Messrs. Baldwin & Adams. They took out a clean 600 ounces, which was sold to Sonnberger & Lane, amounting to $1,800. The mine belongs to T. Z. Armstrong and A. Baldwin, who paid W. H. Collins some $300 for the claim nearly one year since. Mr. Adams leased Armstrong's half of the mine last fall.

NIAGARA.—Tuesday we had a call from Mr. H. Von Bremen, manager of the Niagara Co.'s mines, from whom we obtained the following information. The Von Bremen mine is shut down, on account of its not paying. The Dolly Varden mine is being worked, with fair prospects of developing into a paying property. They have run a tunnel from the river 100 ft, and have struck the seams and commenced hydraulicing.

INYO.

BISHOP CREEK.—Inyo *Independent*, March 11: From Chas. Hollenbeck, superintendent of the Laura mine, I learn that the mine is looking well, and that the mill is being completed as rapidly as possible. An extra force of 20 Indians has been put to work on the road now being constructed from Waucoba to Saline valley, and, as soon as it is completed work will be commenced upon the rich extensions of the Laura.

MINING VISIT.—Supt. Jas. Cross, formerly of Mammoth, at present in charge of an extensive mining work at Candelaria, accompanied by Mr. Andrews, another experienced mining man, were in town yesterday. They took a look at some mines across the river, and will probably inspect several other properties before returning home. Mr. Cross gives positive assurance that the Carson and Colorado railroad management intends to push the road to and through this valley with all practicable speed, and says that the work is going on now as fast as possible.

KERN.

MINING INTERESTS.—Cor. Inyo *Independent*, March 11: The mining interests of Kern county are looking bright. Those of Indge Colby have been purchased by the Hirshfield Bros., of Bakersfield and Tehachipa. In the Long Tom mining district, some 25 miles northeast of Bakersfield, on Posey creek, they have a 10-stamp mill, which is running under the supervision of Mr. Webb, an old resident of Kernville. The ore pays $10 per ton, and there is about 400 tons on the dump. There is a contract unlimited for more ore at $4 per ton, timbering the mine included. The price paid for the mine in the way of trade was $100,000. The Yukum mine, that there was much trouble about a few years ago, when Tucker and Johnson lost their lives, is being worked with good results. Also some new mines lately discovered are developing fairly. Taking everything into consideration, the Owens River country has a fair rival in the Posey district in the way of mines.

MARIPOSA.

COMPROMISE.—Mariposa *Gazette*, March 11: The Compromise mine at, Marble Spring, is reported by several gentlemen of large mining experience as being one of the best mines west of the Rocky mountains, and I believe it to be so.

GRUB CULCH.—Cor. Mariposa *Herald*, March 10: Improvements are advancing in a quiet way. New roads and new mining discoveries keep up hope and an anticipation of a bright day dawning upon our laboring classes of now idle men. The mines in and about Grub Culch are prospecting very well.

THE RED ROVER is now down about 50 ft, the vein growing larger and richer as they go down. They are getting splendid prospects, and the mine is daily enhancing in value, and bids well to the shareholders for a bonanza.

THE Gambetta and McDonald mines are considered to be good. Considerable prospecting is being done all over the country hereabouts, with, in many instances, very flattering results.

I AM told the General Garfield mine, near Metcalf's ranch, prospects well for surface rock. The vein looks well and is about 2 ft thick, with another vein, showing fine sulphurets, in about 4 ft above it. It is owned by John Strebie and J. M. Duncan. We believe there is a large area of good mining country out here. If know of no better field for prospectors to strike a bonanza than in this part of the country.

NEVADA.

THE GOLD POINT.—*Foothill Tidings*, March 8: Work is going steadily forward on the new prospect known as the Gold Point, located southeast of the Idaho Mt. Co's ground. A shaft is being sunk and is now down 40 ft. The shaft is 11x5½ ft in the clear, and shows a most promising ledge. Mr. James Bennalleck is the superintendent of the company, and, under his management, the mine will undoubtedly be speedily developed. Five men are now employed on the property, and before many weeks the force will be greatly increased.

SCOTT'S FLAT.—Cor. *Tidings*, March 8: Scott's Flat assumed a lively appearance; it's all hustle and work. Jacobs & Co., of Quaker Hill, set likewise their hydraulic powers to work, and the hillsides have to come down. Mr. Turner, of Hunt's Hill, was one of the first who got up metal and waded in to search for this precious metal. Mr. McCloud and his sons followed suit. So you see the world will soon be once more enriched by that stuff which makes mankind so mean.

I was told that in the Murchie mine, on Deer creek, above Nevada City, they had found well-paying rock, better than ever before found in that mine. There is also a slight rumor of having found a new quartz ledge, somewhere in this vicinity, though I know no particulars about it.

HOMEWARD BOUND MINE.—Grass Valley *Union*, March 9: The enlargement of the incline shaft from 2 to 3 compartments has been completed from the surface to the Menlo tunnel, where a large station has been opened. At the bottom of the shaft, 283 ft deep, the north drift is being extended from the point reached by the working of the old company. A ledge of good-looking quartz shows in the drift.

SIERRA.

SEVENTY SIX.—*Mountain Messenger*, March 11: The Seventy-six Co., near the Pliocene shaft, have their tunnel in gravel, and find the bedrock pitching away from them, demonstrating that they are much too high. The length of the tunnel run is about 600 ft. The company worked rich ground in a lower tunnel, but the bedrock raised so rapidly that they were compelled to run another, which is, unfortunately, as much too high as the other was too low.

PAT.—Jack Billings has found some very good pay gravel in his diggings at Sebastopol. He has taken out as high as $30 a day, 2 men working.

RUBY.—The Ruby Co. has run some 600 ft east from the shaft at the end of their main tunnel, but have not yet struck any gravel. They are working from 15 to 20 men.

RAINBOW.—The Rainbow, at Chips Flat, have got better air by opening into the old works away below. They found a long stretch of the tunnel standing, and in as good order as the day it was run.

RUBY.—It is reported that the Ruby Co., of Carriboo ravine, have struck gravel in their drift from the shaft.

GEO. ORR, the man who was so severely hurt in the Bald Mountain mine last week, is on the mend, and his recovery is considered only a matter of time.

BUNKER HILL.—John McDonald, of the Bunker Hill mine, Little Grizzly, was in town this week. The company is not doing much just now because the water used in its air blast is frozen. The claim is paying well.

NEW MILL.—D. B. Keyes and others, owners of a quartz mine of gold and silver, at Antelope neck, Sierra valley, have made arrangements to have a 6-stamp quartz mill erected upon their property in the near future. The rock assays about $60 a ton in gold and silver.

SHASTA.

SUSPENDED.—Shasta *Courier*, March 11: The Conger prospecting shaft at Eagle creek is down 130 ft. Work has been suspended until the rains are over.

TRINITY.

OUTLOOK.—Trinity *Journal*, March 11: The mining outlook is at present reasonably favorable, and the general expectation is that the hydraulic miners will have an average season, with a fair average yield.

NEVADA.

WASHOE DISTRICT.

CONSOLIDATED VIRGINIA.—*Enterprise*, March 12: On the 1050 and 1750-levels are still cleaning out and repairing the drifts and winzes connecting with the old Con. Virginia shaft.

CALIFORNIA.—On the 1050 and 1750-levels are still cleaning out and repairing the drifts and winzes connecting with the old Con. Virginia shaft.

SIERRA NEVADA.—On the 2700-level drill hole No. 1 has been extended 175 ft, and the joint Union Con. east wieze has been sunk and timbered 10 ft.

OPHIR.—During the week 28 tons of ore have been extracted from the croppings.

MEXICAN.—On the 2700-level the main north lateral drift has been extended 18 ft, and is now being timbered up; on the main south drift are cutting out drain and cleaning up. West crosscut No. 1 has been extended 12 ft.

UNION CON.—During the week 124 tons and 400 pounds of ore have been extracted from the 2500 and 2700 levels.

SUTRO TUNNEL.—Two shifts of repairmen have been employed since last report near point 10,400 retimbering and repairing. They put up 17 sets and three posts of new timbers, and removed 27 sets and seven posts, besides repairing and bracing other timbers and making general repairs. Between sections 108 and 172 a few repairmen have been repairing the track near this point, and bracing down the main boxes and filling in around them so that the cold water will run over them. No work has been done in this tunnel since last report.

YELLOW JACKET.—The pumps have been kept running at five strokes per minute since the last weekly report. The water this forenoon is 95 ft above the 2300-level station, and is evidently reaching the elevation of its head, as it has risen but 9 ft during the past five days, and but 18 inches in the past 24 hours. Five strokes per minute was the speed required to keep the mine free of water before the extra flow from the Excbequer mine came. The pumps at five strokes throw 800 gallons a minute. At seven strokes and with the assistance of hailing tanks we can discharge 1,500 gallons per minute. No other work is being done in the mine at present.

COLUMBUS DISTRICT.

NORTHERN BELLE.—*True Fissure*, March 11: A total distance of 93 ft has been added to the main shaft since sinking was commenced, 9 ft of progress being made for the week. The fourth shaft level presents very much the same appearance as at time of last report. Twelve ft have been added to the depth of the main winze, the total depth on an incline being 102 ft. There is no material change in the other shaft levels, the adit and the levels above looking about the same as a week ago, and are producing the usual quantity of ore. The daily yield of ore has been about 53 tons. Both mills are running steadily and doing good work. Bullion shipments on March account amounted to $15,325.85 to the 9th instant.

MOUNT DIABLO.—The stopes above and below the third level are looking well. That on the second level above the west drift is showing an improvement. A 12-inch ledge of $65 ore has been opened in the winze connecting the second and third levels, and the outlook at this point is favorable. The ore near the center of the mine, below the second level, is opening well and is looking encouraging, an average of the ore pile giving an assay of $132 per ton. A bunch of good ore, assaying $125, has been encountered while extending an old stope above the first level near the shaft. Bullion shipments for the week have been $9 408.71 on the 4th instant, and $6,705 90 on the 7th instant.

EAST MOUNT DIABLO.—The drift into this property from the Mount Diablo shaft is being pushed forward very energetically. Harder ground has been encountered during the week, yet fair progress has been made. The end of the drift is now 37 ft beyond the dividing line of the two mines.

GENERAL JACKSON.—Considerable ore is being extracted from the stope, appearances indicating that the yield will be good for an indefinite time.

CHERRY CREEK DISTRICT.

BETTER TIMES AHEAD.—White Pine *News*, March 11: There is no denying but the present dull spell is being keenly felt by our people; but we should remember we are no worse off in this respect than the people of our sister towns throughout the State. Indeed, it is not at all probable that the present business stagnation will last over a month or six weeks at the farthest. Spring will then have fairly opened, and a revival of our mining industry will loom up. By that time the Star will have opened out its 700-level, which, it is confidently expected, will place the future of that property on a solid foundation. The Exchange and Teacup companies are also getting their business affairs straightened out and will most likely resume work before the 1st of May. The San Jose Co will very likely start up their mill and increase their mining force by that time. At Ruby Hill it is almost among the certainties that a live company will take hold of the valuable mines there and begin their development at an early day. The Silver Canyon mine is are also likely to pass into the hands of capitalists who will work them on a systematic scale. So that really the prospects of this section of the county for the coming season are as good as at any time in the past. We see no cause for despondency.

CENTRAL DISTRICT.

REDUCTION WORKS CLOSED.—*Silver State*, March 9: The Winnemucca Reduction Works, after a run of nearly seven months, were shut down yesterday for repairs. The proprietor, Mr. Alex. Wise, has teams engaged in hauling ore from the Keystone mine, in Central district, to the works, which will start up again as soon as repaired, and there is sufficient ore on hand to run them a month or two.

EUREKA DISTRICT.

STRIKE IN THE EUREKA CON.—*Sentinel*, March 12: It has been rumored during the last three weeks that bodies of ore had been encountered in the Eureka Con. mine, and that the new find continued to improve as it was uncovered. The same rumor was heard again on the streets yesterday, and comes to us from several different sources so directly that there seems to be no doubt of its correctness. Ore has been found in upraises from the 900 level, and in several places also below this level. The ore found is rich ($800 per ton) carbonates, with streaks of black sulphurets running through it. The extent of the ore bodies discovered is not yet determined; it is believed to be considerable, though at present the showing is not what the bears would call a "bonanza." The rise in the stock recently is accounted for by this ore discovery. Still there has been no deal. During the whole time in which the stock was climbing up from $10 to $19 50 there were comparatively few shares sold, probably not more than 1,000 changing hands.

ESMERALDA DISTRICT.

A NEW ERA IN MINING.—Esmeralda *Herald*, March 12: The starting up of the Humboldt mill and the successful operation of the same has given a fresh impetus to mining in Esmeralda district, and the coming summer promises to be an active one. Mine owners can now get their ore milled at a reasonable rate, and they have not lost much time after the mill was started to take advantage of the opportunity. During this week the Crocket and Ophir mines have been leased to several of the most experienced miners of our district, and they are already actively engaged taking out ore. Although there has been considerable rich ore in sight in the former, the property was lying idle for about fifteen years, there being no milling facilities which would warrant the owners to extract it. The Ophir is a late discovery, ore in paying quantities being found only about a year ago. It being rumored about that there was a very important change in the appearance of the Centennial ledge, a representative of the *Herald* made a special visit with a view of ascertaining the exact condition of it. At a point about 340 ft below the tunnel, in the incline (which had been pretty well cut and broken for several ft), is found to go down at the same nice, regular dip as above, and have the same smooth, hanging wall, the ledge being the full thickness of the winze and carrying considerable gold. The most encouraging thing is that the owners realized from the proceeds of about 20 tons of the best ore, which they were compelled to remove while putting down the winze, enough money to pay for all the work done, the whole body passed through, remaining intact. Besides what they have milled from the winze and drifts, there is now over 100 tons on the dump. The owners of the New Esmeralda are busily engaged taking out ore.

LEWIS DISTRICT.

THE NEW MILL.—Lewis *Herald*, March 8: On Thursday afternoon the boilers at the new mill were heated up, and about 40 pounds of steam raised. The new engine was started and moved off smoothly and without a hitch. The engine run a couple of hours to the perfect satisfaction of all concerned. During the trial of the engine, L. M. Pugh of the Lewis Hotel made his appearance with a basket on one arm and a couple of boxes of cigars under the other. All hands joined Lew in a bumper of champagne and something a little harder, wishing success to the builders and owners of the Highland Chief mill, and that the sound of her stampe might be heard through the canyons of Lewis for many a day.

STARR-GROVE.—The south drift from the Clark incline, in the Starr-Grove mine, has been advanced 11 ft during the week ending Saturday, March 4th—total length 18 ft. The ledge has not changed, and carries considerable black metal. The north drift on same level has been advanced 6 ft during the same period.

CHLORIDE.—The main tunnel on the Chlorido mine has been advanced 16 ft—total length 507 ft for the week ending March 4th. The ledge has not changed in appearance since last writing.

SUN BEAM.—The winze from the lower level of the Sun Beam mine is still in good ore, and about 50 pounds of the ore is on exhibition at the office of J. P. Courtier.

BETTY O'NEAL.—The stopes in the Betty O'Neal mine are still turning out the usual quantity of ore, and from appearances are liable to do so for some time to come. The ledge in the south lower level still improves both in quality and size. We understand the ore will be hauled to the mill as soon as the weather moderates sufficiently and the roads are in passable condition.

HIGHLAND CHIEF.—The miners in the Highland Chief mine have all been laid off till further orders from New York. The pumps will be run for the present and the mine kept in condition to start at any time. The Bothwell incline has attained a depth of 277 ft, and the south drift from the second station is now in 95 ft, with seams of good ore running through the breast. The quartz is very hard and differs in appearance from that taken from the Starr-Grove mine.

STAR DISTRICT.

RICH ORE.—*Silver State*, March 11: A carload of ore from the De Soto mine, at Star, was shipped to San Francisco recently. The whole load, something over 10 tons, averaged $922 30 in silver, and $15.07 in gold to the ton. This ore came from the only mine in the county that has been opened over 300 ft below the surface.

ARIZONA.

CLIFTON.—Cor. Arizona *Star*, March 9: The Longfellow Copper Mining Co. have let a contract for work to the amount of $50,000 on the extension of their railroad to their mines. Fifty or 75 miners can get work in this camp at from $3 to $4 per day. J. J. Stevens & Sons, the owners of the Copper King mine, have run in a tunnel 20 ft on their mine, and struck a vein of copper glance and pyrites of copper. They are now in 9 ft on the vein and are unable yet to tell the extent of the discovery.

ELLSWORTH DISTRICT.—Cor. Yuma *Free Press*, March 11: Some new and valuable mines have been found, and the old ones are developing beyond expectations. The Socorro, belonging to the Oro M. & M. Co., is turning out high-grade ore, and the whole ledge will mill at a good profit. The main shaft is down about 50 ft and the ore is steadily improving with depth. The Oro, which is the property of the same company, looks extremely well. At a depth of 65 ft water has been struck in the shaft, which was somewhat surprising to every one, but gives new life to the camp, as we can now calculate on an abundance of water for hoisting and reduction purposes, without expense of transportation. So far the ore below the water line is free milling, containing an exceedingly small percentage of sulphurets. Developments in the Yellow Jacket mine are creating a great deal of excitement, uncovering a body of ore as fine as one would care to see. The shaft is down 25 ft, showing a 3-ft ledge gradually widening with depth. The Good Luck is another mine which is coming to the front and will, in time, show we have silver as well as gold ledges. The ledge is large and a says well in gold and silver. In fact, there is no place in Arizona where there are so many mines, and when capital once takes hold of this district it will prove to be one of the leading ones of Yuma county and even the Territory. The whole camp is busy and all are doing their best without waiting for Capital or any other man to perform their work.

IDAHO.

STRIKE AT BULLION.—Wood River *Times*, March 8: A report of a strike in the Jay Gould mine, at Bullion, has been in circulation during the past few days. The *Times* is, however, reliably informed that the strike was made in the long drift being run in Jay Gould ground, near the line of the Mayflower, and at a point somewhere between 250 ft and 300 ft westerly from what has hitherto been considered the main ore vein or channel, not only in the Jay Gould, but in the Mayflower, Bullion and Ophir mines as well. This drift was started, early last fall, in search of the foot or westerly wall of the vein, which had not been satisfactorily defined. Owing to the opinion which has heretofore prevailed about the narrowness of our veins, it was generally believed that the west wall would be reached in 20 or 30 ft, at farthest. When, however, over 200 ft were run without any sign of a wall, grave doubts arose as to the correctness of the opinion above referred to, and many competent miners expressed the belief that the (supposed) western vein on which the O. K. and other mines are located was only the other or missing wall of the vein. The correctness of this theory remains to be proved by an underground drift which shall connect the workings in the easterly and westerly series of mines. But, whatever may be demonstrated by such a drift—if it is ever run—the fact remains that no foot wall has yet been found to the Bullion vein, and that a second ore channel has just been discovered. This new find is 18 inches thick, of solid galena, rich in native silver.

MONTANA.

THE ALTA MONTANA CO.—Helena *Independent*, March 11: One of the most serious drawbacks to the successful operation of the reduction works at Wickes during the past winter has been the need for a larger quantity of water than their ditches have supplied. With the spring warmth on the hills there will be a sufficient supply for temporary use, and before the season dries up the surface flow, there will be plenty of it coming through the long conduit, which is nearly completed in Spring gulch. With all adverse circumstances incident to the cold season, progress has been made in the manufacture of bullion. The smelter has produced for the month of February 1,-131 bars, weighing 130,387 lbs., carrying 30,374 90 ounces of silver and 233.06 ounces of gold. The amalgamating department has turned out during the same time 7,423 ounces of silver and 16.12 ounces of gold. With an adequate supply of water the concentrator can do much more effective work, and it is expected that the bullion output will be much more largely produced, and the works here more certain of continuous and economical operations.

BARKER DISTRICT.—Cor. Helena *Independent*, March 11: Mr. Maddox, of Boston, President, and Mr. Tillinghast, of Chicago, Treasurer, of the Clendenin M. & S. Co., of Barker district, arrived on this evening's coach, having been unexpectedly called here by the untimely death of Col. Clendenin, resident manager and secretary of the company, at Barker. These gentlemen come to perfect arrangements who eby the operations of the company may be continued, the death of Col. Clendenin, who was the inaugurator of the enterprise and its leading spirit, having caused a temporary suspension of the work. This company has invested an immense amount of capital in the Barker district, and has, under the superintendence of Prof. N. A. Foss, erected a smelter with a capacity sufficient for all the present needs of the company. Actual work has demonstrated that it can successfully and profitably handle the ores. The presence of Messrs Maddox and Tillinghast is evidence that the enterprise so successfully commenced will not be allowed to lag for want of attention or ample capital.

THE LAST CHANCE LODE.—Important developments have recently been made by Messrs. Merrill & Shaef in sinking a shaft on the Last Chance lode in Pioneman mining district. Samples of ore from the vein—which is 3½ to 4 ft wide—assay as high as 413 ounces per ton in silver, and $34 per ton in gold. The prospect is owned by the above named gentlemen, who are now running a tunnel in on the lode.

NEW MEXICO.

THE TORRENCE.—Socorro *Miner*, March 8: Last Sunday a representative of the *Miner* made a pilgrimage to the Torrence mine. Almost half way up the side of the mountain the mouth of the shaft is situated, and is sunk to a depth of nearly 300 ft. There are two drifts or levels, from both of which immense quantities of silver-bearing spar are taken. The lowest level, however, is said to be by far the richest lead, and is developing better all the while. At present no ore is being raised in consequence of putting in new machinery, etc., but men are still working regular shifts beneath, mining and breaking the rock ready for hoisting. A new engine and boiler have been put in place, much stronger than the old ones and with greater capacity, which will be in running order in a few days. About 75 men are employed there at wages ranging from $2 75 to $3.50 per day, and in a short time it is intended to double the force. The greatest inconvenience experienced there now is the scarcity of water, which has to be hauled a distance of 2 miles; but it is anticipated that water will soon be struck at the bottom of the mine sufficient to meet the demands at the top, and which can be hoisted at very little expense. A railroad has been surveyed from the stamp mill to the mine, work upon which will probably be commenced in a very short time. The Torrence is one of the best developed mines in the Territory and is said to be netting its owners $1,000 a day. It practically settles the question of profitable mining here, and furnishes ample proof of the fabulous sums hidden in these mountains, awaiting only the advent of capital and enterprise to find them. The Robinson mine, 3 miles west of the city, is down over 100 ft and is said to be developing fairly. They are putting in a new engine and hoisting machinery, and will be raising large quantities of rich silver-bearing quartz in a short time. They claim to have struck the same lead which is now being worked by the Torrence. The mountain in the vicinity of the Torrance and Robinson mines is covered with prospect holes, which some day will undoubtedly be valuable.

CLIFTON.—*New Southwest*, March 11: Clifton is experiencing a genuine boom. Claims are being actively worked. Dr. Welsh is nearly done laying pipe for his hydraulic works, and the Longfellow Mining Co., is laying track for a narrow-gauge railroad from the Longfellow mine to the Coronado, 6 miles distant. Clifton has enough copper bid in her hills to supply the world.

SILVER CITY.—Some important sales will soon be made in Silver City mining property, and the near future will behold a marked change in the management of mining property in this community. The Sherman mine has already taken a jump, and under the efficient superintendence of Geo Henderson, a gentleman of long and successful experience in Nevada mines, it will soon be producing as much bullion as any mine in the Territory. We are informed that the famous Black Hawk mine, the property of W. Jay Porter and others, was sold yesterday for $100,000. The deeds are in escrow, and the sale will be consummated in 30 days. The bargain, if concluded, will be a good one for both parties, and we congratulate them and Grant county. Mr. Shedd makes the purchase for Eastern parties. Judge Potter and others have sold their Carlisle mine, at Steeple Rock, Grant county, for $110,000, the purchasers being Wm. A. Farrish & Co., owners of valuable mining claims in Colorado, and the Grand Central mine, at Tombstone, Arizona. A full force of men with 3 wagon loads of supplies were sent out on Wednesday to commence operations, and we may soon look to that district for bullion.

OREGON.

NOTES.—*Sentinel*, March 11: Will Q. Brown, of San Francisco, has purchased the mining interests of Wm. Briggs, near Canyonville, for $700—copper and nickel. .....The Sterling Hydraulic Co. is piping day and night, with a moderate head of water, the continued cold weather in the mountains preventing the melting of the snow and a full water supply..... All the miners on Sardine creek are busy ground sluicing with full heads of water and making good wages.....Cale & Cowan have some rich ground in the Birdseye claim on Foot's creek, and manage to pick up considerable gold from the bedrock.....Joe. Anderson is now running the '49 claims with excellent prospects.....Chas. Howard is engaged in a survey for the large ditch being constructed by Gin Len, from Palmer creek to the Red hills.....From every point of Josephine county we hear that miners are busy with an ample water supply and making up for lost time. .....All the large hydraulics on Galice are now working day and night.....A clean-up that turned out well is being made at the Applegate gravel mine..... The large reservoir being constructed by the Squaw Lake Co. is nearly completed.....The king bolt in the "giant," of Chappel & Co.'s claim, was displaced one night this week, by the wearing out of the threads, and the pipe of the giant was blown quite a distance, the piper barely escaping a serious injury. Damages have been repaired and work goes on as usual.....Green Bros., of Josephine, are running their anastras on very rich quartz with a large supply in sight.

UTAH.

HORN SILVER.—*Southern Utah Times*, March 11: The Horn Silver mine is shipping from 14 to 16 carloads of ore per day to Francklyn, besides keeping 2 stacks running at Frisco, which will take at least 4 carloads per day, making an average output of 18 to 20 carloads of ore per day. Several new strikes have been reported in this and adjoining districts within the last few days, but we have not been able to obtain any particulars for this issue.

Cellular Growth of Plants.

Last week we had an illustrated chapter on the growth of the tree and the formation of wood. Upon this page we pursue cell growth fnrther, using for this purpose an illustrated paper recently read at the Academy of Sciences by Dr. H. W. Harkness, as follows:

In presenting, as I propose to do this evening for yonr conoideration, the vegetahle cell and eome facts pertaining to its life history, I ehall rely upon the recorded observations of Mohl, Sachs, Cohn and others and shall claim no originality for myself, nnless it be in the manner of illustrating the snbject.

This tiny speck of matter is year hy year assuming greater importance and is heing eagerly scanned hy men of science. When we take a retrospective view of the progress which has heen made in this line of investigation within a recent period, we have good reason for helieving that the patient and close obeerver will he rewarded, hy bringing to light many new and valuahle discoveries—discoveries, too, of such a nature and of so mnch importance as to to cast a flood of light upon many of the nnsolved prohlems pertaining to hoth animal and vegetahle life. For in this little, tiny cell is to he fonnd the physical hasis of hoth animal and vegetahle life.

To the cell and its multifarious transformations he must turn, would he wish to gain a knowledge of the growth of the trunk, the circulation of the sap, the formation of the leaf, the flower, the fruit, while on the other hand would he seek the ultimate molecnle of matter, he must marshal the forces contained within the cell, and from the cell itself go hackward to granule, from granule to cytohlast, from cytohlast to fluids, from fluids to gases, and from gases to the spectre—haunted chambere of analytical hypothesis.

The greater number of cells in snconlent plants are composed of three distinct layers, first, an outer firm investment which is desig-nated as the cell wall, and which consists of a suhstance peculiar to itself, termed cellulose. In close proximity to the cell wall lies a second memhrane of far greater interest, the primordial utricle, or protoplasmic sac. This is an exceedingly delicete memhrane formed from protoplasmic matter, and contains within its walls all of the protoplasm.

As a free hody within this protoplasm, we find the nuclens, or cytohlest, an object of great and growing importance. This hody is now supposed to have an independent invsstment of its own.

For the purpose of more clearly illnstrating this portion of the suhject, I will compare it to an object very familiar to all of you—an egg.

The shell of the egg well represents the cell wall, the lining membrane. The amnion, fitting closely to the shell, will represent the primordial utricle, while the delicete allantois or vitelline memhrene, inclosing the yelk, shall represent the investment of the cytohlast. We have all observed that the amniotic memhrane lies in such close contact with the shell of the egg as to seem a part of it, yet if the egg he carefully dried we find that as desiccation progresses the memhrane separates completely from the shell, and shrinking upon itself still continues to protect its contents.

Were we ahle to make sufficiently accurate observations of partially dried plants, we shonld douhtless find the utricle shrunken in a like manner upon its contents, hnt as our instruments fail us here, we may arrive at the same resnlt by a different mode of procedure.

If we take a thin longitudinal section from near the center of the stem of a calla, and placing it upon a glass slide, allow a few drops of strong sulphnric acid to come in contact with it for a few seconds, we find that the primordial ntricle has completely seperated itself from the cell wall and, with its contents, is completely exposed to our view, as in Fig. 1. If the acid is allowed to remain a few seconds longer, the cell wall is ohliterated and the utricle and its contents set free, and in a condition much like that of the dried egg which hes heen denuded of its shell. The cell contents may now hs examined, and, with the help of chemical reagents, its constituent elsments pretty accurately determined. A positive and complete analysis can hardly he hoped for; hut it is highly probable that, like the colorless corpuscle of the hlood, it contaios all of the elements needful for the repair of waste and the huilding up of new tissue.

Those cells which lie immediately heneath the cuticle are crowded with granules of chlorophyll, while those lyiog deeper contain more or less starch.

Fig. 2 is designed to exhibit these cells, which give to plants their green color. Fig. 3 shows cells filled with starch grannles, a thin slice of potato heing used for tbat purpose; hut as starch granules in their natural colorless state do not show to good adventage when mounted in fluids, I applied a weak solntion of iodine, which has changed their color to a heautiful hlne. Many of the starch cells will he found empty, haviog heen divided hy the rezor in makiog the eection; the etarch hee heen washed out of them.

Amoog the maoy curioue and interesting facts already known regarding cell life, the circulation of the cell eap is one of the moet curioue. This muet not he confonnded with the general circulation of sap in the plant, from which it is entirely distinct. This movement, called cyclosis, or cell rotation, is a rotary motion of flnide contained within the walls of each individnal cell. It is shown in Fig. 4, in which the direction of the movement is indicated hy arrows. A cnrrent of fluid moves along the cell wall until, reaching an angle, it strikes the next wall, when it turns, and, hy another route, finde its way hack to the starting point. This movement seems to he necessary to the well-being of the protoplasm, as if interrupted for any considerahle length of time the protoplasm loses its vitality. This action is in progress in every cell of the growing portion of every plant, unless checked hy external influences, and when we try to realize the aggregate power exerted, we can hut admire this as an amazing instance of the results produced hy the unseen forces of Nature.

When we consider, that in the millions of cells of each growing plant, in meadow, forest and etream, this movement goes on withont panse or cessation, we are ahle to appreciate the glowing langnage nsed hy Huxley in describing this phenomenon: "Were onr ears so attuned that we might hear these tiny maelstroms, the aggregate volume of sonnd would exceed the roar of a Niagara."

It has recently been discovered that a mild cnrrent of electricity arrests this movement; and here permit me to digress for a moment, in order to say, that in my opinion, recorded many years since, thie cell circulation is checked, if not altogether arrested, by the action of our northerly winds. In support of this, I will etate hriefly one or two of eeveral facts wbich go far to prove the trnth of this theory. Anyone who has observed growing plants dnring the prevalence of northerly winds, mnst have noticed that they ehrivel and cnrl hefore the hlast, ehowing signe of the greatest distress, even if the wind has been blowing bnt for a short period; on the retnrn of the soft, moist wind, however, the plants resnme at once their fresh and vigorous appearance.

These changes can be dne neither to desiccation on the one hand nor to ahsorption on the other, they are far too sudden for that, hut they are no doubt attrihntahle to the temporary cessation of cell rotation, brought ahont hy the electrical disturhances which we know take place during the continuance of theee winds.

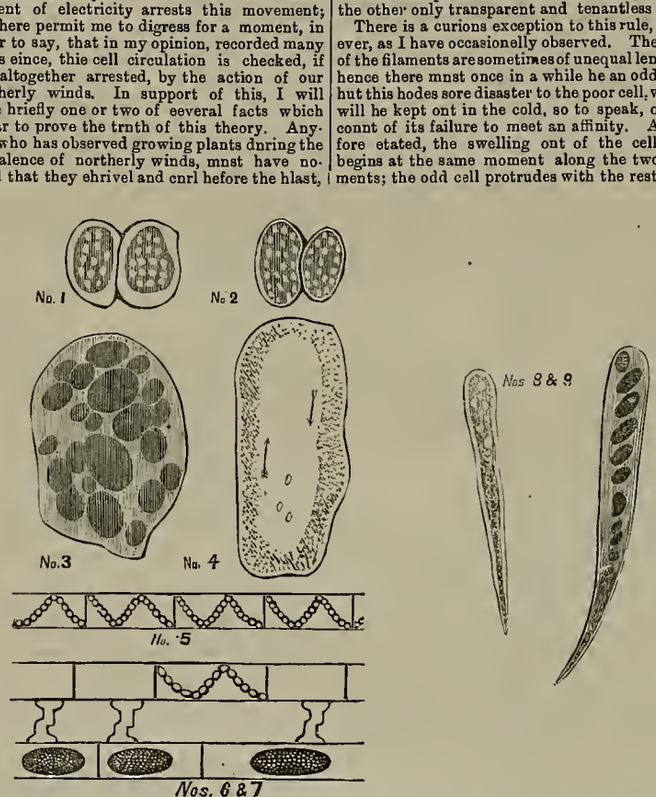
The process of the multiplication of cells varies somewhat, according to the situation and reqnirements of the plant. In a few hnrried remarks made at onr previons meeting, I hriefly described the process of cell multiplication hy subdivision, as it takes place in the protophyte or unicellnlar plant. I then stated that in most of the protophytes the division was either hinary or qnateroate, and that this was the simplest form in which we were ahle to study the process. Ipropose this evening todescribe and so far as possible, illnstrate the formation and growth of the cell in two or three species of a higher order of plants. I have here hefore me a well-known plant called hy botanists *Spirogyra longata*, hy the children frog's hit, which heloogs to a very large order of plants—the Conjugata, so celled hy reason of the method of formetion of the germ cell. This is a long filamentous plant, made up of a large nnmber of cylindrical cells joined together at their extremities; see Fig. 5. The protoplasmic contents of these cells coneist of chlorophyll grenules, colorless glohules, plasmic fluid, and one or more uuclei or cytohlasts. The granules of chlorphyll are arranged in a heautiful spiral within the cell, and give to the plaot its vivid green color.

Multiplication by Conjugation.

The manner in which the germ cell ie formed in this plant is extremely intereeting, and serves to illustrate that of all the speciee belonging to the family. The process may he readily obeerved by anyone who is the possessor of a microscope, and the reqnisite amount of patience. The plants may he found in the proper stage of development in small pools of fresh water dnring the last days of Febrnary and the earlier part of March. In the plants collected during thie period, the following process may he observed: It mnst be remembered that the plant is simply a row of cells. In two plante lying beside each other, slight swellings appear npon the eides of those cells which are contiguous. These protuherances grow in size until they meet and coalesce; immediately after this union, the walls of both are ruptnred at the point of contect, forming a free pessage hetween the two cells (see Figs. 6 and 7).

At this moment the protoplasmic contents of each cell shows eigns of great excitahility, the chlorophyll grannles immediately separate and destroy the beautiful spiral threads, and mixing with the rest of tbe protoplasm, present for a time an appearance not nnlike that of stsel filings nnder the influence of a megnet. After a short time, however, the contents of one cell rushes through the opening into the other, where the protoplasm of hoth instantly combine to form a germ cell of the most vivid green. This process is hsing repeated in every cell at the same moment of time, and as the result, we have in one plant a row of vivid cells, and in the other only transparent and tenantless ones.

There is a curions exception to this rule, however, as I have occasionelly observed. The cells of the filaments are sometimes of unequal lengths, hence there mnst once in a while he an odd one; hut this hodes sore disaster to the poor cell, which will he kept ont in the cold, so to speak, on acconnt of its failure to meet an affinity. As hsfore etated, the swelling ont of the cell wall begins at the same moment along the two filaments; the odd cell protrudes with the rest, hnt



CELL GROWTH AND MUTIPLICATION AS SEEN WITH THE MICROSCOPE.

he is doomed to see the cells opposite him affiliating with his neighhors of the right and the left, while he is left forlorn (Figs. 6 and 7). In a short time, however, the swelling subsides, and he snbmite gracefully to the inevitahle, becoming a "hachelor cell." So far as we can judge, however, he ssems to rather enjoy the situation, at least for a time; he still retains his heautiful spiral of green, is still an object of admiration and attention, and the eye falls upon him at once, on examining the locality. Hie companions have all gone over to the other side and left him, on either hand, a long row of tenantless ahodes. Finally, however, he assnmee a yellow-janndiced hue, resnlting, it may he, from disappointment, then rapidly decays.

These germ cells, so curiously formed, are not at once set free from the parent cell, hut they are retained within the wall of the now dead plant for days, sometimes for weeks, should the conditions prove nnfavorahle. Were they eet free at once they wonld he in the exact condition of the egg denuded of its shell. Instead of this, they are retained and protected nntil a cell wall has formed from the cell contents. This heing accomplished, the water having meanwhile evaporated, this germ is ready with the first favoring breeze to start ont upon its travels.

I need not say to yon, ladies and gentlemen, that ths little plant I have so feehly described is cosmopolitan in its hahit. A germ so well protected and at the same time more huoyant than thistle down, may, when aided hy favoring winds, he wafted across oceane or continents, and ie equally at home in the pools produced hy the meltiog snows of the Himalayas, as it is on the slopes of the Sierras.

The procese I have describsd is termed "cell multiplication hy conjugation." The next in order of importance is that which is termed

Free Cell Formation,

The procese of which ie thus described hy Seche: "In the protoplasmic hody of a cell new centere of formation arise, around each of which a portion of the protoplasm gatbers and forms a cell." In illnstrating thie procese I shall make use of a fnngoid plant, of the order Sphæriaceæ, discovered by me a few days since as a parasite upon the hnckeye. This plant is developed heneath the cuticle of the hark, the firet intimation of its prssence being a slight nodular swelling upon the hranch on which it has fastened. Soon after its first appearance a nnmher of microscopic secs arise from the stroma. These sacs, which are represented in figures 8 and 9, are filled with delicate protoplasmic granules with several nuclei or cytoblasts. These "motber cells," ae they are termed, all develop, in this particular plant, eight germ cells, neither more nor less, in the following manner: At some point in the mother cell we notice a hright spot, or granule, around which a portion of the protoplasm begine to collect and, hy growth and accretion, soon assumee the form of a germ cell. We are often ahle to witness this process in all stages of its development within the walls of a single mother cell, and we may arrest this development at any stege and preserve it for study, as you will see in the specimen nnder the instrument. As in the former instance, these cells remain within the parent cell until the investment of each has hecome consolinated into a firm cell wall, when it too is set free.

Although the process lacke tbe dramatic force of the preceding one, yet it marks a decided advance in the scele of plant developmsnt.

Lighting Mines by Electricity.

In Europe they are doing a good deal more experimenting in the matter of developing the possibilities of the electric light than we are in this country, yet we are by no means idle here. It may interest our inventors as well as the mining community to know that a prizs of $2,500 has heen offsred to the person who produces the best eystem of lighting mines by electricity. This offer comes from Mr. Ellis Lever, of Manchester, a gentleman who has shown a great and practicel desire to improve the position of the working miners of Great Britein, and give them the greatest possihle amount of safety whilst following their employment. Such an offer cannot fail to find a good many competitore at the present time, when so much attention is hsing devoted to electricity for almost every purpose in which coal and gas have hitherto been the principal agents.

Aside from this premium, of course it is well understood that a great reward awaits the inventor of a miner's electric lamp, hecause eo very many would be used. The London *Mining Journal* relates that already lamps have heen tested in some mines where a good deal of gas is given off, and that with a fair amount of success for what may he tsrmed first attempts. In such an application of electricity it ie necessary that the light ehould he entirely cut off from all communication with the air eurrounding the lamp, and for this purpose the Swan eystom has heen found effective, for hy it a nnmher of the lamps can be placed singly in a circuit. The light from an electric lamp in a mine hes been fonnd to he equal to from 12 to 15 candles. The lights proceed from the incandescence of a fine fiher of carhon, the comhustion of which is prevented by its heing inclosed in an exheusted glass hulh. The lamps were inclosed in lanterns which enehled the fragile glass hulhs to he carried ahout without liahility to accident. At one place where the lamp alluded to was tried it was particularly admired hy the workmen for its brilliancy in whatever nosition it was placed, and requiring scarcely any attention whatever. The electricity was supplied by the cnrrent of an ordinary Gramme machine, driven hy a portable engine placed near the top of the upcast-shaft; hut there is an easier method, no douht, for it can he stored up and taken down in a mine and the lamp replenished as reqnired. Seeing that the lampe at prcsent in use not only give a very dim and dismal light, but have heen credited with well nigh having heen the cause of many of the fatal explosions which have taken place at different times, there is every likelihood that they will he repleced hy those lighted hy electricity, and that before long, and for this purpose the indncement held out hy Mr. Ellis Lever cannot fail to he taken advantege of hy those specialists who are now engaged in electrical iuvestigation.

Life Insurance.—We cell attention to tbe advertisement of the Pacific Mutual Life Insnrance Co., in another column. Thie compaoy has for Directors a gronp of well-known and respected citizens of California, and they announce the following as characteristics of their orgaoization:

1. Since its organization, A. D., 1868, it has paid 395 death losses, on policies amounting in the aggregate to $1,098,237.
2. It has paid to policy holders, for matured endowments, dividends and surrender values, in round numbers, $1,600,000.
3. It has repeatedly been examined by sworn experts, and most thorough and searching investigations made of its condition and business, and in every case its solvency and trustworthiness have been demonstrated.
4. Its stockholders and directors are widely known as among the most capable business men and ablest financiers of the State of California, and the integrity of their management is unquestioned.
5. The laws of the State, including the constitutional provisions affecting corporations, are of the most rigid character, such as to make the company one of the safest institutions of its kind.
6. Its policy contracts contain no restrictions upon residence or travel, and its forms of insurance are unusually attractive. The low rate, deposit endowment, and mutual investment policies, are peculiar to this company, and offer advantages to the insured which are not surpassed, if equalled, by those of any other company

The Engineer.

Institute of Mining Engineers.

The annual meeting of the Institute of Mining Engineers recently held in Washington, was well attended and very interesting in its character. It was not conspicuous for scientific interest, but the papers were varied, and all dealt with topics of current importance. The discussion was free and animated, and while not developing any new or startling facts in science, was instructive and interesting. The discussion on tests of iron and steel as structural material, was of immediate and practical interest in view of pending legislation, and expresses very freely the views of engineers and manufacturers of iron and steel as to the necessity of continuing the work begun by the U. S. Commission, which expired, by the failure of Congress to make an appropriation to meet its expenses, about the time the great testing machine now at the Watertown arsenal was finished. The importance of creating a new commission with larger powers and better defined objects, has been brought to the notice of Congress in a bill just introduced, which will receive the hearty support of the entire profession.

It is expected that the next meeting will be held in the far West, partly because many Western members desire such an opportunity to visit the Rocky mountain region, and partly as an accommodation to members in the mining districts of Colorado, Arizona, Nevada, California and other far Western States and Territories, who have hitherto been required to come long distances to attend the meetings.

The Institute is rapidly growing in numbers and influence, and its active membership somewhat exceeds 1,000. Mr. R. P. Rothwell, E. M., was elected to the presidency for the ensuing year.

ANCIENT ENGINEERING.—The ancients, when all is said and done that can be in favor of modern prowess and progress, knew a few things that we moderns have no sort of conception of. In a late celebrated work on architecture, the author says that not only is it impossible to duplicate the great temples of Athens, but it is inconceivable how they were constructed. The same may be said of the temples and the pyramids of Egypt. The Roman roads were superior to any constructed in modern times. Their very remains are stupendous. The ancient canals of India and her immense water reservoirs, including their sites, are incapable of being improved upon. In fact, the very ruins of the ancient are "tremendous." One of the latest discoveries of the wonderful engineering ability of these ancients is the fact that, in preparing to cut a tunnel through the Isthmus of Corinth, it has been brought to light that the Roman Nero, as notorious for his cruelty as for his love of the arts, sciences and literature, had engineers upon the same spot; and more, that the route selected by them has been selected by the engineers now having charge of the modern undertaking. But Nero was preceded by Alexander the Great in the attempt to carry out the colossal undertaking, and, in both instances, the engineers showed themselves to have thoroughly mastered the conditions required for the inception of the work.

RAILROAD CONSTRUCTION IN THE UNITED STATES FOR 1881.—The Chicago *Railway Age* has submitted its statistics of railroad construction in the United States during 1881 which show that the track has been laid on 258 different lines, aggregating 8,242 miles—the largest mileage ever constructed in any one year—that for 1880 having been 7,174 miles, which was greater than that of any previous year, except 1871, when the total reached 7,379 miles. Of the 42 States and Territories in which the work of railway building was prosecuted in 1881, Texas takes the lead with 1,411 miles; Iowa follows with nearly 500, while Maryland is credited with only 25 miles of new railroad, Georgia with 54½, Alabama with 14, Arkansas with 109, Florida with 103, Kentucky with 143½, Louisiana with 236, Missouri with 229, Mississippi with 68, North Carolina with 149, South Carolina with 67, Tennessee with 37, Virginia with 273, and Dakota and Ohio with between 400 and 500 miles each. Of the total mileage, 1,490 miles, or about 14% were narrow gauge lines. With the exception of Texas, through which the Southern Pacific has been pushing its way, the Southern States scarcely make the showing that was expected.

A TUNNEL UNDER THE MEDITERRANEAN.—The latest engineering project is a proposition from the Venetian society of public works, which has asked the government for authorization to make surveys for a project of railway communication between Sicily and the main land by means of a submarine tunnel under the straits of Messina.

A USEFUL WOOD.—One of the hardest woods in existence is that of the desert ironwood tree, which grows in the dry washes along the line of the Southern Pacific Railroad. Its specific gravity is nearly the same as that of lignum vitæ, and it has a black heart so hard, when well seasoned, that it will turn the edge of an axe and can scarcely be cut by a well-tempered saw. In burning it gives out an intense heat, and charcoal made from it is of unequaled quality.

Useful Information.

Celluloid Printing Plates.

Another new and most important application of celluloid has recently been introduced into this country in the form of celluloid printing plates. This process has already been successfully practiced on a large scale in France, where it is at present attracting considerable attention. A French inventor, M. Jannin, has succeeded in producing remarkable results in products of celluloid printing plates, both from wood engravings and from type. These are said to possess great fineness, and to be considerably more durable in service than either metal stereotypes or electrotypes. The process consists in taking a copy of the engraving on wood or of the type, with the use of a special cement, which hardens rapidly and takes the finest lines sharply. After about 20 minutes this cement is hard and resistant. The press in which this first impression is taken should be slightly heated, and a sheet of celluloid is employed to obtain a counter impression from this, which is then prepared by ordinary methods for the printing press.

M. Jannin is reported to have succeeded by his method in obtaining marvellously fine results, and is now engaged on a large scale in making celluloid reproductions of letter text, engravings of all descriptions, bas-reliefs, medals, and imitations of carvings in ivory. The work is executed very rapidly. A plate can be made within an hour, while to make a good electrotype by the usual process requires from 12 to 15 hours. A celluloid plate has been subjected to 25,000 impressions, apparently without losing any of its sharpness.

When used as a substitute for wood in the production of large printing type, it is found to be much preferable to wood. It has a fine surface, possesses great durability, can be readily worked, is light, and can stand all the rough usage of the job press.

A NEW MANUFACTURE.—A new and curious branch of the silk manufacture has lately crept into some Paterson factories. The process is a secret, and no information can be given about it, as every safeguard is maintained to prevent its getting out. The weavers themselves alone possess the secret, which is not even imparted to their employers. They work in a small room, closely locked on the inside and out, so that no one can see how the curious loom is worked. The work is said to require great skill, and only a few weavers can do it, who consequently demand and receive very large wages. Whether the thing is a success or not remains to be seen, as none of the goods have yet been placed in the market. Some of the samples that have been exhibited, however, are said to have created a decided sensation. The goods produced are nothing more or less than imitation seal skin, made of silk. It is a new process, and entirely different from the manufacture of velvet or plush, or anything of that sort, and the product is said to so closely resemble genuine seal skin of the finest quality as to deceive even experts. It is quite expensive, although of course nothing to be compared with real seal skin. The future of this branch of the silk trade remains to be seen. If the product is really what it is represented to be, it is a big thing, and will doubtless prove exceedingly profitable to those possessed of the secret of its manufacture.—*Paterson Guardian.*

GUNPOWDER WITHOUT SULPHUR seems at first rather a startling proposition. All the world over gunpowder is, and has always been, made of three ingredients—saltpeter, sulphur and charcoal—and it seems rash to attempt to do without any one of them. But experiments were made a good many years ago with sulphurless gunpowder, and the result astonished the experimenters. The old "*eprovette* mortar," which was then used to prove the quality of powder, gave as good results with the non-sulphur powder as with the ordinary kind. But the manufacture of gunpowder was at that time in a crude and unscientific state. There were no such tests for density, and so on, as now prevail; so the experimenters made their non-sulphur powder too light, and abandoned the pursuit, thinking that it was in its nature porous and weak in texture. The subject comes up again under new conditions, both of manufacture and of tests for various qualities. We understand that in England under the direction of Sir William Armstrong powder lately made without sulphur has given very good results in guns. The subject seems worth pursuing.

BLACKING BRASS.—A correspondent of the *English Mechanic* says: I have tried all the various recipes recommended—nitrate of silver, platinum bichloride, etc.—but never found any work so satisfactorily and cheaply done as by the reduction of nitrate of copper to the oxide. I find the best way of using is to apply the solution to the brass to be blacked with a camel-hair brush, previously slightly heating the metal; then to raise the heat until the requisite color is produced; finishing by rubbing with a soft rag, and either oiling or lacquering. I can confidently recommend this as the very best method of producing that good black seen in first-class optical goods, observing that the process will not do for soft-soldered articles, as the heat necessary to produce the black is greater than the melting point of soft solder.

TO CLEAN PAINT.—The following directions, says the *Manufacturer and Builder*, are simple, and will be found to answer very satisfactorily for cleaning paint on woodwork: Provide a plate with some of the best whiting, and have ready some clean warm water and a piece of flannel, which dip into the water and squeeze nearly dry; then take up as much whiting as will adhere to it, apply it to the painted surface, when a little rubbing will quickly remove any dirt or grease stains. After this wash the part well with clean water, rubbing it dry with a soft chamois. Paint thus cleaned is said to look as well as when first put on, and the operation may be tried without fear of injury to the most delicate colors. It is said to answer far better than the use of soap, and does not require more than one-half the time and labor. Another simple method is the following: Put a tablespoonful of aqua-ammonia in a quart of moderately hot water, dip in a flannel cloth and with this merely wipe over the surface of the woodwork. No rubbing is necessary. The first recipe is preferable, except where the paint is badly discolored.

PEAR WOOD.—The timber of the pear trees is of a yellow color. Gerard says the timber of the wild pear is very firm and solid, and good to be cut into molds. The platee for his "Herbal" were cut out of this wood, as were, says he, breastplates for English gentlewomen. At the present day it is much used by turners and pattern makers; the blocks with which the designs for floor cloths are painted are made from pear wood. When dyed black it can scarcely be distinguished from ebony. Handles for carpenters' tools, measuring rules, etc., are made from this wood. The wood of the pear makes excellent fuel, giving out an intense heat with a bright flame.

PACKING.—A compound of india rubber and asbestos, which is to some extent a new combination, is now used as packing for valves, its peculiar properties rendering it particularly fit for this purpose. For range valves, or high-pressure hot-water cocks, it appears invaluable. As it contains no wire it can be cut to any required size, and will stand any temperature; at present it is used most for packing steam joints and large valves.

PAPIER MACHE for dome construction seems to be now the universal idea. Two or three observatories in this country are soon to be provided with *papier mache* domes; and it is now pronounced that the dome of the Colossal Palais de Justice, Brussels, approaching completion, which was to have been of copper, shall now be constructed of papier mache. It will weigh about sixteen tons.

Good Health.

Dreams and Their Conditions.

Dreams are night thoughts, unchecked by the judgment and uncontrolled by the will. It is not true that we do not reason in dreams, that the exercise of the judgment is wholly suspended and that the will is entirely powerless or ceases to act. These faculties are not altogether in abeyance, but they doze while the subordinate powers of the mind—those which play the parts of picture carriers and record finders—ransack the treasures of memory and mingle together, in the direst confusion, old things and new. Imagination is not active, but it remains just enough awake to supply the connecting links which give seeming continuity to those parts of the phantasmagoria which we chance to remember on recovering perfect self-consciousness, and which, being remembered, we call "dreams." No one remembers more than one dream, unless he has roused from sleep more than once. This experience has led to the inference that dreams only occur at the moment or in the act of awaking. There are dreams which take place in the process of returning to consciousness—for example, those instantaneous scenes and spectacles which are suggested by the sound or feeling that rouses the dreamer; but, in result of a long and close study of the subject with a view to discover the nature of dreams and the laws of dreaming, for medical purposes, in connection with the treatment of sleeplessness, I am persuaded that dreams occur in the course of sleep and are wholly forgotten.

That they do not and cannot take place in deep sleep is probable, because deep sleep is general sleep, and when this state prevails the subordinate faculties are sleeping, and the pictures and records which compose dreams are not disturbed. To understand dreams we must understand sleep, and it is because the two phenomena have not hitherto been studied together that so little is generally known about either.—*Popular Science Monthly.*

How to Apply the Soda Remedy in Burns and Scalds.

It is now many years ago (see the London *Medical Gazette* of March, 1844) that the author of this paper, while engaged in some investigations as to the qualities and effects of the alkalies in inflammations of the skin, etc., was fortunate enough to discover that a saline lotion, or *saturated* solution of the bicarbonated soda in either plain water or camphorated water, if applied speedily, or as soon as possible, to a burned or scalded part, was most effectual in immediately relieving the acute burning pain; and, when the burn was only superficial, or not severe, removing all pain in the course of a very short time; having also the very great advantage of cleanliness, and, if applied at once, of preventing the usual consequences—a painful blistering of the skin, separation of the epidermis, and, perhaps, more or less of suppuration.

For this purpose, all that is necessary is to cut a piece of lint, or old soft rag, or even thick blotting paper, of a size sufficient to cover the burned or scalded parts, and to keep it constantly well wetted with the sodaic lotion so as to prevent its drying. By this means, it usually happens that all pain ceases in from a quarter to half an hour, or even in much less time.

When the main part of a limb, such as the hand and forearm, or the foot and leg, has been burned, it is best, when practicable, to plunge the part at once into a jug, or pail, or other convenient vessel filled with the soda lotion, and keep it there until the pain subsides; or the limb may be swathed or encircled with a surgeon's cotton bandage previously soaked in the *saturated* solution, and kept constantly wetted with it, the relief being usually immediate, provided the solution be saturated and cold.

What is now usually sold as bicarbonate of soda is what I have commonly used and recommended; although this is well known to vary much in quality, according to where it is manufactured—but it will be found to answer the purpose, although, probably, Howard's is most to be depended on, the common carbonate being too caustic. It is believed that a large proportion of medical practitioners are still unaware of the remarkable qualities of this easily-applied remedy, which recommends itself for obvious reasons.—*Popular Science Monthly.*

Action of Coffee and Sugar in Digestion.

M. Leuen makes a report before the Paris Biological Society of the effects of these articles of food, in connection with Dr. Semerie. There is great diversity of opinion on these subjects. Some, as Trousseau and Pidoux, consider coffee an excellent digestive. Others, on the contrary, consider it very injurious.

M. Leuen thus writes: He mixed 30 grams of coffee in 150 grams of water, for a dog, which is killed three hours after. The mucous membrane of the stomach is found pale, discolored and profoundly anæmic. The vessels on the internal surface, as well as those in the peripbery, are contracted. There remains 145 grams of the mixture undigested, and the stomach digestion diminished, because the contraction of the vessels, and the consequent anæmic condition of the mucous membrane, prevent the secretion of the gastric juice. The abuse of coffee will produce dyspepsia. Thus the English and the Dutch, who drink freely both of tea and coffee, are very dyspeptic. Coffee increases the cerebral functions, an effect useful, agreeable and innocuous.

Sugar has been denounced by modern chemists as a substance whose effects on dyspeptics are deplorable.

Dr. Leuen does not partake of these fears. He cites the case of a dyspeptic doctor, who for 20 years had a terror of sugar, but who now consumes 120 grams (3¾ ozs.) of sugar daily, without inconvenience. He followed similar experiments with sugar. A dog ate 80 grains of sugar with 200 of other food. Six hours afterward its stomach showed little food. The mucous lining of the stomach was red and highly congested. The congestion of the liver was notable. If one opens an animal after eating 200 grains of food and no sugar, 90 to 100 grams of food is undigested. Sugar, then, favors the secretion of the gastric juice. Coffee sweetened loses part of its defects.—*Le Medecin Practicien.*

HEALTH IN MIDDLE AGE.—At the age of 35, says a writer in the *Family Doctor*, mankind, according to some eminent authorities, is said to have reached the meridian of life, while others name 40 as the middle year of our earthly existence. But, he the case as it may, no one who has taken the ordinary means to preserve his health in youth and early manhood should feel other than young at the age of 45, from which period until that of sixty, if life be spared to us, we shall do well to consider ourselves middle-aged, and to adopt greater precautions for the preservation of health and consequent happiness, than might have been deemed necessary when youth was on our side. And if this is done, the period of middle age should be one of the greatest activity of both body and mind. What though the hairs are turning gray? That but shows one has suffered sorrow and survived it, or that, sorrow apart, he is a man who thinks. And what though the limbs he not quite so nimble? Calm enjoyments foster thought and general habits of that true temperance which conduces to long life and contentment more than anything else in this world; and whatever some may say to the contrary, I maintain that the desire to live long is inherent in every healthy sane man or woman. To die of old age is the only natural death, and if death may ever be said to be pleasant, the only pleasant one. Though younger than some of my professional brethren still in harness, I have nevertheless seen death in many shapes and forms, and in almost every case I have found the aged more resigned to the inevitable than those less advanced in years. For a well-spent life is like a well-spent day—at its close there is a wish for rest.

Passing Events.

The past week has been the most eventful of the winter, in one respect, at least, as the abundant rains have fallen all over the State. This insures a prosperous year for California, and one of profit to both farmers and miners. With a good supply of snow stored in the mountains, the miners are assured of a good season's run.

Already the prospectors are getting ready to start out on expeditions in every direction. The newer regions will this season be most vigorously prospected, as there are many more persons now interested in the mining industry than was formerly the case. These men will scatter over the mountain ranges and hills in their search for ore, and no doubt hundreds of valuable mines will be discovered. We shall next week issue a special edition for prospectors, which they will find very useful to them.

There is no specially noteworthy event among the mines worthy of mention. The current mining news is given in our "Mining Summary" in a very condensed form, and embraces all that is going on over a wide region.

THE next party of miners to Mexico will not be sent forward from the Comstock until the first lot are heard from, which will be about 10 days hence. Mr. Deidesheimer will accompany the next party, which will probably consist of 250 men. It is said that the company which has been hiring these miners expect to have 3,000 men at work by the first of June.

Iron Pipe and California Iron.

It is stated that a syndicate has been formed in London for the purpose of purchasing the Blue Lake system of water, with the intention of furnishing this city with water. Some time ago State Mineralogist Henry G. Hanks forwarded the syndicate his annual report, giving an analysis of the "Clipper Gap" iron ore. Other information was also forwarded by Mr. Hanks, and he has received this week a letter in which the following statements occur: "Should the city accept this liberal proposition, the syndicate proposes to put up extensive iron works in the harbor of San Francisco to roll the plates for making 137 miles of iron pipe, and I am frequently called before them for information, and among other important inquiries is: Is there iron ore in the State convenient (or on the coast) for making steel, without phosphorus or other substance injurious to steel. In the work you sent you give the analysis of the Clipper Gap iron ore, which is particularly good, but as it is so situated as to be dependent on the railroad for transportation * * * it could not probably be utilized for this purpose. Will it be asking too much of you to inform me of any deposit of iron ore convenient to the bay, and also an analysis of the ore? The rolling mill would at first run the Bessemer pig iron from here, but would want, as soon as it could be economically done, to either stimulate the manufacture of pig iron by others or put up furnaces themselves. The machinery would be built strong enough to make steel rails when the contract for making the steel plates for the pipe had been completed. As I hope to induce the building of the iron works, even if the city does not take the water, I will thank you for any information you can give me that will be of interest to those considering this project. The best engineers of the country have considered the scheme and estimated the cost of putting 50,000,000 gallons per day in reservoirs provided by the city at $17,500,000. They also estimate the cost of such a plant as they would want at $1,050,000, which would have a capacity of rolling 4,000 tons per month."

The writer of the above, we should judge, does not know much about the iron industry here. We have a rolling mill in this city now, perfectly equipped. The iron works and foundries here have all the tools and appliances for doing as heavy work as is done anywhere in the world, and can do it as well.

As to manufacturing wrought iron pipe for conveying water, California can probably teach the English a good deal more than they imagine is to be learned. On this coast we deal with bodies of water under conditions not dreamed of elsewhere. Gorges are crossed with what are called inverted siphons and pipe made to stand pressure which elsewhere would be considered impossible. In short, our experience in this line has been peculiar and has been large. Wrought iron pipe for carrying water is now shipped from this city all over the coast, to the Sandwich Islands, Central America, Mexico and South America. There are several firms in San Francisco which make a specialty of manufacturing this pipe, and we are perfectly certain they would make it better and cheaper than people new to the business

As to rolling rails, the Pacific Rolling Mills, in this city, are perfectly prepared to do that. Sacramento, too, would have something to say about that branch. If the English people want to put up Bessemer works here to work up such deposits as the Clipper Gap iron, all very well. That ore, however, has to be brought a long distance by rail. Other deposits would have to be opened. But as to putting up mills simply to roll enough plates to build 137 miles of iron pipe, that is an absurdity. The pipe could be made and laid before the new mills could be got ready. As before stated, neither the English nor anyone else can tell us in California much about wrought iron pipe that we do not know already. Our experience in this direction has been wider than most people imagine.

There are many deposits of iron ore in California, but we are wofully lacking in fuel. Had coal and iron been found here in close proximity to each other, there would have been numerous furnaces working now. The foundrymen of this city would not have been content to use imported iron if it could have been produced here as cheaply; and there is plenty of capital here which would have taken hold of any enterprise with any likelihood of success. It fact the fuel question is the important one. We have to use foreign coal at our rolling mills and at our foundries. The Clipper Gap furnaces are run with charcoal, but it is not everywhere that suitable wood for charcoal is available. Then fluxes must be found, and the question of transportation comes in.

We are afraid our English friend has some visionary ideas. The practical men connected with the iron industry in this city have very thoroughly canvassed this whole question already. The statement that there are specimens of iron ore in the Mining Bureau from Napa, Sierra, Shasta, Placer, Amador, El Dorado, San Benito and other counties, conveys no information of a practical character and is apt to mislead. If there are no fluxes, no fuel, or no means of transportation, the deposits, even if good, would be of no use. There is always a lot of "general principle" talk on this subject, lacking one important element—the practical.

Institute of Engineers.

Several futile attempts have been made in this city to organize an Institute of Engineers. Two or three times the mechanical engineers have come together and tried to perfect an organization, but failed. Perhaps half a dozen or more attempts to form a society of mining engineers have also failed. It is more than probable that this non-success has been due to certain ones taking the lead who were unfitted to harmonize conflicting interests, or rather, jarring elements, and that they rather antagonized some who would otherwise have made good members. At all events, whatever the cause, we have no engineers' society of any kind in this city or on the whole coast. None of the engineers here seem to pull together, each one hanging back like a balky horse, independent of the rest. Whether professional jealousy or simple disinclination to be gregarious keeps them apart, the fact remains that they are apart. And now the young State of Colorado comes to the front with such an organization as we have been trying to have here, and it invites the co-operation of any other scientific association, journals, and those interested in scientific investigations and industries.

The Colorado Institute of Engineers has been organized by the civil, mining and mechanical engineers, chemists and metallurgists of the city of Leadville, Colorado, for the purpose of affording an exchange of scientific ideas, the professional improvement of its members, the advancement of mining industries, the fostering and encouragement of scientific research in the many fields which this country affords, the establishment of a library and reading room of technical works, periodicals, communications and original manuscripts, the collection of a mineral cabinet, and the creation of a central point of reference and union for its members.

Much care has been employed to make the initiatory steps in the formation result in the proper basis for a permanent and reliable association. The encouragement which has been given warrants the originators in saying that they believe the success of the undertaking to be fully assured.

The organization was completed on January 25, 1882, and rooms secured for the Institute in the post office building, Leadville, Colorado. The regular meetings are held at the Institute rooms on the last Wednesday evening of each month. All persons interested, visiting the city, are cordially invited to use the rooms of the Institute during their sojourn. The President is Thos. W. Jaycox and the Secretary, Frank L. Sizer. We hope before long to receive published proceedings of this young society.

Settlers.

Metallurgical settlers are of two classes, one having mullers with wooden shoes, and the other having arms with either wooden or iron shoes or stirrers. For heavy, underground sand, the muller is easier to start and less liable to clog, and is more commonly used in such cases; but for well-ground sand the other style is superior. A settler should never be allowed to foul by an accumulation of heavy matter at the bottom; it is a positive preventive of good work. It may seem easier to advocate this than always to follow it. The seeming natural remedy for such a condition is really an aggravation of it—that is, the liberal use of water. There is a point in the thinning when the quicksilver will be precipitated, but the heavy sand is held in suspension. If, after the charge is run out, which should leave about eight inches in the settler, a pan is drawn and no water added for half an hour, the warm charge will gather and carry the heavy sand; now enough water only is added to reduce it to an appearance of still some thickness, and this is all the water that is used in the charge.

THE Antimony mines belonging to Escalante & Whimple, in Sonora, which were said to have run out and were abandoned by the company which was exploring them, are found to be actually true veins, from which, up to the 20th of last month, more than a thousand tons of metal have been extracted. Equally so with respect to the other mines of the district of Altar and Magdalena that are being actually worked, continue to produce good ore, offering great hopes for the future.

THE Horn Silver mining company, Utah, during the year 1881, produced 16,341,995 pounds of lead and 1,259,903 ounces of silver. A careful estimate, by one of the very best miners on the coast, who is familiar with every detail of the mine, based upon past surveys and measurements, compared with later explorations, places the amount of ore in sight at over $50,000,000.

THE Belcher, Crown Point and Imperial companies, Gold Hill, have given orders to hoist out all tools, air-pipe, car-track, and other apparatus and machinery from points below the level of the Sutro tunnel. This, of course, shuts down the lower levels. The Crown Point and Belcher companies will, however, continue the extraction of low grade ore from the upper levels.

On Minerals.

[Notes of a Lecture delivered before the Mechanics' Institute by A. W. JACKSON, Jr., Instructor of Mineralogy, Petrography and Economic Geology, at the University of California.]

(Continued from Last Week)

Metallites.

Under this general head we comprise all of the insoluble and incombustible minerals that contain a heavy metal as an essential ingredient. This includes all substances ordinarily called ores. A more exact discussion of what an ore is will come later, in my lecture on ores; suffice for the present that an ore is any mineral from which a metal can be profitably extracted. Now, while this class contains about 360 minerals, only about 50 of them are actually available as ores at the present time. The rest either occur in too small quantity (some, indeed, are extremely rarely met with), or are incapable of profitable reduction.

We subdivide into the four orders indicated in the table.

Halometallilis.

This order comprises the combinations of the heavy metals with acid such as—

Silicic,
Sulphuric,
Carbonic,
Phosphoric,
Chlorhydric, etc.

Among the 168 minerals which constitute the order, are some of the rarest and most beautiful known to the science. As a group, they present much livelier and more beautiful colors than the preceding minerals, and with this further difference, that the colors are mostly quite characteristic, the mineral occurring with but one color instead of a dozen or more, as with many of the preceding minerals. The luster is common (stony), but generally very brilliant. They nearly all occur in exquisite crystals, with every conceivable variety of form and grouping. The mode of occurrence is quite characteristic for most of them. They are found in the upper portions of ore deposits.

To glance hastily at some of the individual minerals, we pass by at once quite a number containing the rare elements niobium, tantalum, cerium, etc. Calamine and Smithsonite are the chief sources of zinc. Hornsilver is a very valuable ore of silver, but every old miner knows how it disappears as soon as depth is attained.

Cerussite,
Anglesite,
Wulfenite,
Pigromorphite,
Vanadinite,

Do not figure much as ores of lead, because the sulphide is too plentiful. Naturally, a very large number of iron salts are known; iron itself is such a common element that we find it in combination with almost every acid with which it will form an insoluble compound. Thus we have a large number of silicates, sulphates, phosphates, arsenates and carbonates, of all of which only the latter is of great economic value.

Siderite, in the form of clay, ironstone, occurs differently from the mode indicated above. It occurs in widely extended horizontal deposits, interbedded with coal; so that frequently both coal and iron ore are hoisted through one and the same shaft. It may be said, without exaggeration, that England owes much of her successful material development to this fortunate intimate association of two of the greatest factors of modern civilization, coal and iron. In many of the coal fields of this country, in Pennsylvania, Ohio and the West, this same intimate association is met with, and must furnish the basis of the most enduring prosperity to those favored sections.

Copper has some important ores in this group, particularly the two carbonates, malachite and azurite; the one an exquisite emerald green, and the other on equally beautiful blue. You are all more or less familiar with the former, worked up into the form of vases, table slabs, mosaic and other ornamental work. Nickel, cobalt, manganese and uranium also occur in salts, but the minerals are rarely met with.

Metal Oxides.

The metal oxides are simply combinations of a heavy metal with oxygen, partly hydrated, partly anhydrous.

We meet in this family for the first time minerals with strong *metallic luster*, as in the oxides of manganese, magnetic oxide of iron, and specular iron, while on the other hand, *most* of the oxides have a common lustre, and a considerable variety of color.

The geological occurrence is extremely various, so that nothing of a general nature can be said of them. The oxides of iron (magnetite, specular iron, hematite, and limonite), of manganese, pyrolusite, of tin, cassiterite, also chromite, zincite and cuprite all form extensive ore bodies and are mined in large quantity.

California contains large amounts of Chrome-iron, confined mostly to the coast range. It is all sent East in the raw state. The occurrence of one of these oxides of iron as the universal red, yellow and brown coloring agent of soils also deserves mention. Iron, either in the form of magnetic oxide or combined with a silicate, occurs in nearly all rocks whose decomposition produces soils; and the iron invariably finds itself ultimately in the form of insoluble brown, yellow, or red, hydrated oxides, which are almost universally disseminated.

Some Suggestions as to the Formation of a Mining Association.

In a communication to the MINING AND SCIENTIFIC PRESS, (published December 31st, 1881), on the "Hydraulic Mining Question," certain facts were presented for for consideration concerning the importance of the hydraulic mining industry and the probable results of its enforced abandonment. Hydraulic mining is only one branch, though the most important one, of the California mining industries. Drift mining of the auriferous gravel banks, either as an auxiliary to the hydraulic mining of the same deposits, or independent of it in gravels that cannot be profitably worked by hydraulicing, employs a large amount of capital and labor and adds considerably to the total annual gold product of California. Quartz Mining and milling also employs directly and indirectly a still larger amount of capital, and are the support of a large population.

In the suits now on trial in Sacramento, and in the unreasoning feeling aroused in the purely agricultural regions of the State, which threaten the very existence of hydraulic mining, can be seen the germs of a movement to destroy or greatly cripple the entire mining industry. This is not yet openly avowed, in fact, would probably be denied, but granting for the moment that the fight against hydraulic mining is successful, and it be either entirely stopped or subjected to such conditions as to make it unprofitable, how long will it be before drift mining is attacked? Unquestionably, the same law and evidence that will operate against one will work against the other. Drift mining is gravel working on a very small scale, yet the aggregate of debris discharged into the rivers is very large. Some single drift mines wash from 50,000 to 100,000 cubic yards annually, and it is probable that the drift mines on the Middle Fork of the American river run yearly nearly as much gravel as the hydraulic mines tailing into it. In what way quartz mining can be attacked is not so clear; it would be a far-fetched course of reasoning that would claim direct damage to valley farming land from it, yet so sympathetic is all mining enterprise to an attack on one branch, that it would doubtless be greatly injured.

That sand and gravel will be taken up by the rivers in the mountains, and carried by them to the valleys to be there deposited, is undeniable. The rivers certainly won't transport sand and gravel the other way, and unquestionably the hydraulic and other mining done in the mountains furnishes the rivers with a large proportion of the material with which they fertilize the valley lands. The present mining is not, however, responsible for all the damage claimed to have been done by the river deposits; the placer mining of 20 and 30 years ago is even more a factor in filling the river channels with sands and gravels, which every winter's high water washes over the low banks and leaves on the land.

The issue has been very squarely put by the farmers and must be met as squarely by the miners. No mere words can disprove the fact of overflowed debris-covered farms, for which hydraulic mining has a partial responsibility. Nor will mere words or theoretical discussions of the value of slickens as a fertilizer for bottom lands compensate the farmer for the practical destruction of his means of support. Whether the debris can be held back in the mountain canyons and prevented from spreading over the valleys is entirely an engineering problem, but admitting as most probable that it can be successfully solved, it will not afford immediate relief and is therefore only a part, though an important part, in a general, comprehensive scheme of action on the part of the miners. It should also be realized that any plan of action depends, both for inception and carrying out, on the miners, unaided by any other interest, probably with all other interests and whatever political power they can wield opposed, and unpalatable as it is, the opposing elements represent the greater political power.

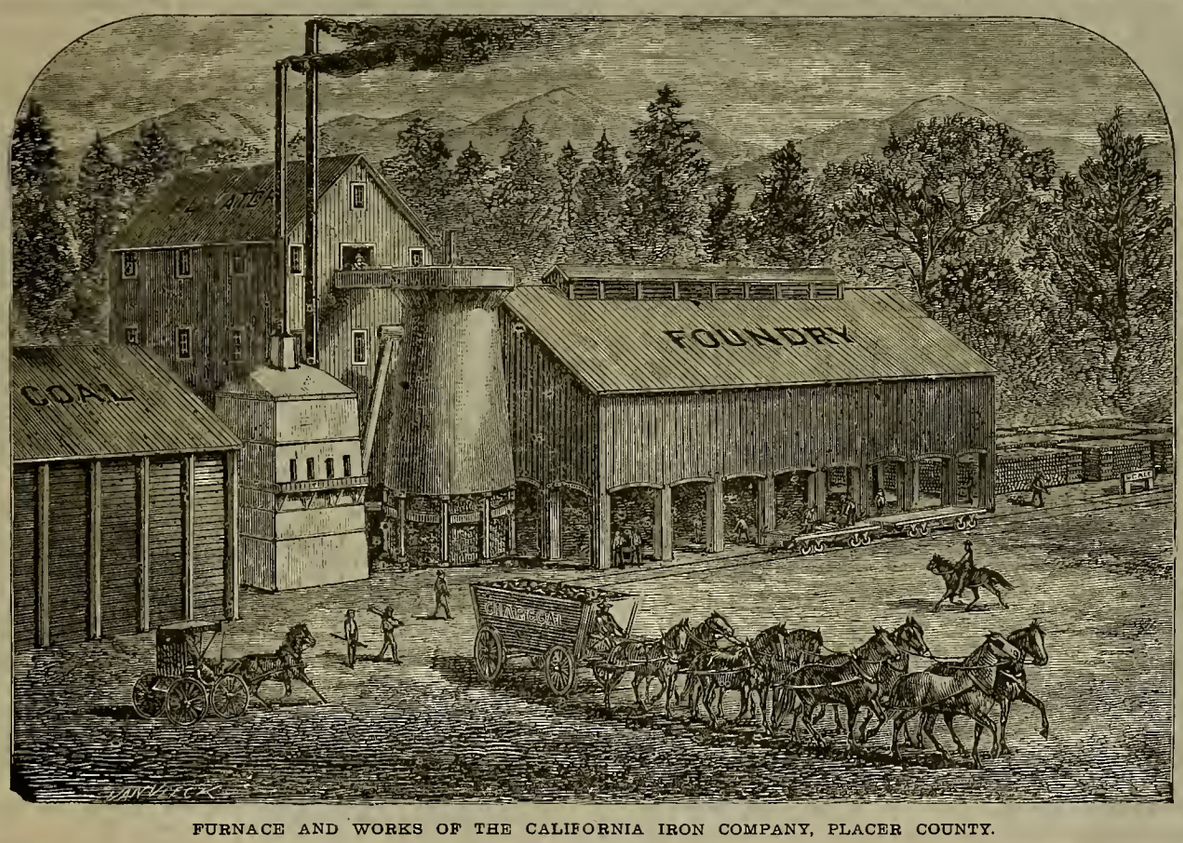
The suggestions, or rather plan, I have to offer by those more familiar with the problem to be solved may be deemed impossible of practical application, but it is at least pertinent in view of the miners' meeting soon to be called, and possibly may have the plea of novelty. It, if considered practicable and adopted, would go far toward ending the present agitation by restoring confidence between the two great industrial interests of the State. Its practical operation would tend to prevent a recurrence of the causes leading to the present trouble, and incidentally mining would be placed on a firmer basis, and relieved of much of its necessarily speculative character.

Briefly stated, the plan is about as follows: Let a miners' association be formed that will admit all mine owners, whatever the nature of the mining they are engaged in, and ditch owners in the mining counties. As the basis of association, let each mine owner, or owners, and ditch owners, list their mining property to the association at their own valuation, the right to membership to be vested in and to pass with the title to the property so listed, such valuation to be the measure of representation in the councils of the association, and for the assessment of the general dues for the support of the association. The control of all general and executive business to be placed in an elective board of directors. In addition to the board of directors, let there be two other elective boards, independent of the board of directors, and of each other. The first to be known as the Board of Condemners, whose business it shall be to visit the districts affected by the debris from the mountain streams, and ascertain a fair valuation for the injured property. The board of directors shall, on the report of the board of condemners, be empowered to purchase the condemned property at a price not in excess of the valuation decided on by the Board of Condemners, the title to all such acquired property to vest primarily in the Association, as trustee for the mines and mining property assessed for its purchase, ownership to be in proportion to the amount of tax paid. The third board to be known as the Board of Assessors, whose duty it shall be to determine annually the proper valuation for all mining property listed to the association, as a basis for a tax to be levied by the board of directors to secure funds for the purchase of condemned lands and for such general engineering works as may be practicable for holding the debris in the mountain canyons, and for leveeing and improving the purchased valley lands. Also, this board should determine the ratio of tax for which each piece of property is liable. The general funds and dues—these taxes noted being special funds—would be used for the payment of salaries and the defense of such suits as that now on trial in Sacramento.

As an auxiliary to the association let some of our rich mining capitalists establish a strong mining bank, in which the association and individual miners could deposit their funds. Then let the bank confine itself to an exclusively mining business, dealing in and making loans only on mining property. Such an institution would greatly strengthen the mining interests of the State, and be a financial success, backed up by such an association as proposed.

Naturally enough there are defects in this plan of operations, which would be certain to some extent to militate against its practical success. Most of these defects are, however, due to the nature of the problem dealt with, and are of necessity inherent in any plan that may be proposed. Large amounts of money would be required, but could be raised in the method indicated without crippling the industry, as would be the case if no action is taken and adverse litigation is successful.

The Spring Valley hydraulic mine has successfully put in operation a portion of the details of the plan I have proposed. In the MINING AND SCIENTIFIC PRESS of Dec. 31st, 1881, will be found a long article descriptive of the mine and the method the owners took to solve the slickens problem. Briefly summarized, during the ten years from 1870 to 1880; $395,196 were expended in the purchase of 6,000 acres of land subject to damage from the mine debris, and $154,708 for levees and other improvements, giving practical control of all the tailings from the mine. The total expended in this way was $549 904, about 20% of the gross yield of the mine. During the same period, $465,000 were paid in dividends. During eighteen months of 1880 and 1881, $21,400 have been expended for levees, etc.; $50,000 disbursed in dividends, and about $240,000 in wages and mine expenses. There has been no slickens litigation, nor is any probable



FURNACE AND WORKS OF THE CALIFORNIA IRON COMPANY, PLACER COUNTY.

Lime Instead of Powder in Mines.

For breaking down or getting coal or other minerals in mines and quarries, Messrs. Smith and Moore propose to use caustic lime, introduced into bore-holes in the said minerals, and then brought into contact in a confined condition with water, so that by the expansion of the lime in becoming slaked, and by the pressure of steam generated, considerable force is produced, sufficient to effect the breaking down of the mineral. By this means, in the case of coal mines, the double advantage is gained of effecting the breaking down of the coal without danger of explosion of fire-damp, and with the production of a greatly reduced proportion of small coal as compared with the ordinary blasting operation. Their invention may be carried into practice in a variety of ways, but according to the arrangement and mode of operating they employ, by preference, the caustic lime is ground fine, and then consolidated by pressure into cartridge form, each cartridge having a groove on the side, which cartridges are inclosed in waterproof casings to protect them from damp. A solid rod or needle is first inserted into the bore hole; the cartridges are then introduced, the surface of the groove being next to the needle, and they are rammed home to insure their filling the bore-hole. After the cartridge or cartridges have been inclosed, either by tamping with clay or other suitable material, or by a bung or otherwise, the needle is withdrawn, and a tube is inserted in its place, which tube is fitted with a tap or automatic check-valve, or other means of closing it. Through this tube the water is conveyed to the lime by a force-pump, or other power; when the water has been enforced in, the pipe connecting the pump or other power with the said tube is detached, and the tube is closed, so as to prevent the escape of the steam generated by the action of the water on the lime.

In order to cause the whole mass of the cartridge or cartridges to be subjected more or less simultaneously to the action of the water so as to bring about a rapid and energetic action, the cartridges may have a groove, as before mentioned, formed along its side, or a hole through its center, into the front end of which groove or hole the said tube for conveying the water is made to enter, so that the water is forced in along the whole length of the cartridge or cartridges. Or, the tube itself may be made to extend along the whole length of the cartridge or cartridges, and be provided with perforations or slits through which the water can issue. The lime they prefer to use is made from mountain limestone. Although they prefer to employ the lime in the form of consolidated cartridges, as described, yet it may also be rammed into the bore-holes in an unprepared condition, the tube for conveying the water being first introduced into the bore-hole at the side or center thereof; or a solid rod or "needle" may be introduced in the first instance, as aforesaid, and after withdrawing the same the tube for the water supply is inserted in its place. If desired, other fluids, such as diluted sulphuric acid, may be employed, or the water may be used hot to accelerate the expansive action of the lime, and other substances may be mixed with the lime for the same purpose.

Russell L. Dunn.

Auburn, Jan. 24, 1882.

The California Iron Works.

The engraving on this page is a representation of the plant of the California Iron and Steel Company at Hotsling, Placer county. This is the first step towards utilizing the iron ore deposits of this State. In course of time a rolling mill will be the result. We shall in the next number of the PRESS give a detailed description of these works and of the proposed operations of the company.

EXTRA EDITION.—The next number of the MINING AND SCIENTIFIC PRESS will consist of 24 pages, and will be devoted to the interests of "Prospectors." We have compiled and collected a great deal of information valuable to this class of the mining community, and the PRESS of next week will be useful for reference to others as well.

READERS who preserve files of the PRESS for reference, will please observe that, owing to a mistake in numbering the folios, an error of 20 pages occurs. The second page of this issue should have been 170, the third 171, the sixth 174, and the seventh 175.

AN earthquake in Costa Rica destroyed the towns of Alajuela, San Ramon, Greca and Hereda, and several thousand lives were lost.

EXTENSIVE coal fields are being discovered in the districts of Arispe and Montezuma, Sonora. The fields are many leagues in extent and the coal is of superior quality. The State Government of Sonora has issued concessions to two parties for the exploration of the fields.

THE delinquent list of the California M. Co. is the largest ever published on the Pacific coast. About 10,000 certificates are advertised.

TWENTY-FIVE tons of ore per day are being shipped from the Ramsdell Parrot to the Montana Copper company's smelter.

CONSIDERABLE placer ground has been staked off in Rio Arriba county, N. M.

CHICAGO **FRASER & CHALMERS,** ILLINOIS.

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. B. Haggin for Giant and Old Abe Co., Black Hill s also Corliss Pumping Engines, 26x60, for Hoisting and Pumping Works, for 2,000 feet deep. **Baby Hoists for Prospecting, 4 H. P. to 6 H. P.**

Wire Rope, Safety Cages and any Size and Forms of Cars.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail.

HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,750 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. BOILERS of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

McCaskell's Patent Car Wheels and Axles—Best in Use.

TONITE POWDER COMPANY, - - 403 California St., S. F.

VULCAN BLASTING POWDER.

—THE MOST ECONOMICAL AND BEST—

Nitro-Glycerine Explosive in the Market.

In the suit of the Giant Powder Co. against the Vulcan Powder Co. for *alleged* infringement of Patent, it was held that the Giant Powder Patent was INVALID.

Nos. 1, 2 and 3 Vulcan,

Each grade superior to like numbers of any other Nitro-Glycerine Powder in the market.

VULCAN B. B.,

Superior to Black, Judson or any low grade Powder for Bank Blasts, Railroad work, or any work where Black Powder has been heretofore employed.

TRIPLE FORCE CAPS AND ALL GRADES OF FUSE.

The CONSUMER'S COMPANY sell the best Powder at the lowest rates.

Office—218 California St., San Francisco.

THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street - - San Francisco, Cal.

The best of

Through Dewey & Co.'s Scientific Press Patent Agency.

No. 252 Market Street. Elevator, 12 Front St., S. F. Telephone No 658

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long established, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most *reliable* advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free. DEWEY & CO., PATENT AGENTS.

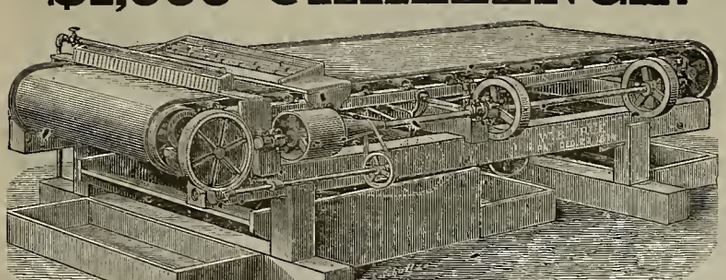
$1,000 CHALLENGE!



THE FRUE ORE CONCENTRATOR.

Nearly 300 are now in use, giving entire satisfaction. Awarded First Premium and Silver Medal at the Industrial Fair for 1880 of the Mechanics' Institute of San Francisco, Cal.

Saves from 50 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal; water required is less than in any other wet Concentrator; the power required per machine is less than one-half horse power; the labor required is light, one man on a watch can attend to sixteen machines.

We challenge any other Concentrator in use for a fair and impartial competitive trial, side by side, for stakes of $1,000 each, and we mean business.

☞A machine with all improvements can be seen in working order and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont street.

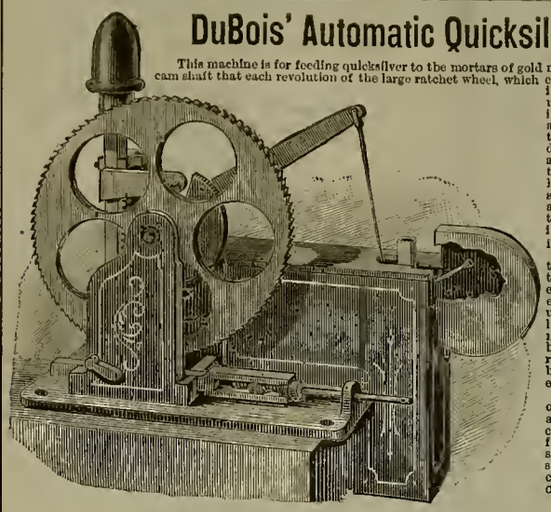
THE STRONGEST BARROW MADE. These Barrows are made by Superior Workmen, and of the best material. All sizes kept constantly on hand
SHEET IRON PIPE.
Lap-Welded Pipe, all Sizes, from Three to Six Inches. Arteslan Well Pipe. Also, Galvanized Iron Boilers, from 25 to 100 Gallons.
Iron Cut, Punched, and Formed for making Pipe on ground, where required. All kinds of Tools supplied for making Pipes. Estimates given when required. Are prepared for coating all size of Pipes with a composition of Coal Tar and Asphaltum.
Office and Manufactory, 130 Beale Street, San Francisco.
SHEET IRON PIPE.

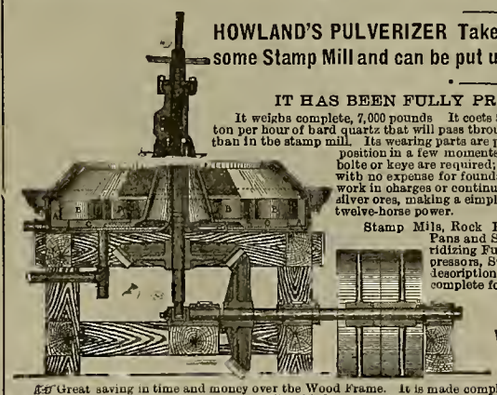
DuBois' Automatic Quicksilver Feeder.



This machine is for feeding quicksilver to the mortars of gold mills. It is so connected to the cam shaft that each revolution of the large ratchet wheel, which can be regulated to revolve once in one, two, three or four minutes, as desired, dips a small cup into a reservoir of quicksilver, and by a trip of the cam, empties the contents into a pipe leading down to the mortar, supplying an exact quantity at regular intervals, superseding the ordinary hand feeding, which is of necessity subject to great irregularity, and liable to neglect. It renders the amalgamation of all the gold in the pulp equally certain and perfect.
The mechanism to produce this depression and elevation of the cup, is driven by the cam shaft, similarly to the self-feeders, over which so much ingenuity has been expended to regulate the delivery of ore to the mortar. As it is to be desired to have the ore go in constantly and regularly, so it is equally desirable to have the mercury fed constantly and regularly.
A chief point of excellence of this machine is, that it allows the quantity of mercury which would be otherwise fed in mass, in one hour, to be subdivided into a number of small portions, and fed almost continuously; *i. e.*, from every one to four minutes.
Price, complete, $100.

For Sale by **WHITNEY & MARSHALL,** Sole Agents
22 & 24 Fremont St., San Francisco.
Dealers in Iron, Steel, Hardware and Mining Supplies, Wrought Iron Pipe and Fittings, Pump Columns, Wire Rope, etc. A large stock of Boiler, Plate and Sheet Iron of every description.

MOREY & SPERRY,
MANUFACTURERS OF
Gold and Silver Grinding and Amalgamating Machinery



HOWLAND'S PULVERIZER Takes the Place of the Cumbersome Stamp Mill and can be put up in one day ready for work.
IT HAS BEEN FULLY PROVED AND TESTED.
It weighs complete, 7,000 pounds. It costs $1,500 ready for the belt. Will crush one ton per hour of hard quartz that will pass through a 40-mesh screen. The wear is less than in the stamp mill. Its wearing parts are plain castings and can be dropped into position in a few moments, as shown by the letters A, B and C, no bolts or keys are required; it can be set upon the floor of a mill with no expense for foundations, and can be used to crush and work in charges or continuous. It will amalgamate either gold or silver ores, making a simple, cheap and effective mill, it requires twelve-horse power.
Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver ores, Chloridizing Furnaces, Retorts, Rock Drills, Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill supplies. Iron Work complete for Wood Frames, also
SPERRY'S WROUGHT IRON FRAME FOR STAMP MILLS.
☞Great saving in time and money over the Wood Frame. It is made complete with Wrought Iron Frame ready to put upon the foundation. We construct Mills with Stamps weighing from 350 to 000 pounds for Gold and Silver Ores, Wet or Dry Crushing Mortars.
MOREY & SPERRY—Warerooms, 92 and 94 Liberty St., N. Y.

LEFFEL'S IMPROVED WATER WHEEL.

Vigorit Powder.

The California Vigorit Powder Company, of this city, has issued a pamphlet containing a report on the powder, by W. R. Quinan, Fourth Artillery, U. S. A., from which we make some extracts, premising that perusal of the complete report (which may he had by addressing the company at 327 Pine street, S. F.) will enable many to learn considerable about the nature of nitro-glycerin compounds.

Mr. Quinan has considerable to say on the several features of nitro-glycerin powders, and powder manufacture generally, and also gives the results of tests made by him. He says:

"Even a properly compounded powder, if not perfectly detonated, will produce noxious gases. Nitro-glycerin itself, if not properly detonated, will produce noxious gases. The noxious gases formed by certain nitro-glycerin powdere are oxides of nitrogen, which affect respiration, and carbonic oxide, which is a deadly poison. But neither is formed when the oxygen is in proper proportion to the other elements, and the powder is susceptible to perfect detonation under the particular circumstances. This freedom from noxious gases was one of the original claims of the old Vigorit powder, and on good grounds. So susceptible is the powder to the action of the fulminate, that even unconfined, lying on the surface of an iron plate, its detonation is perfect, and under these conditions it will show greater strength than a really stronger powder, in which a perfect detonation can only be effected under strong confinement."

Guided by theee theories, and deductions from practical experiment, I have been led to adopt the following formulas for the composition of the different grades of Vigorit powder as best fulfilling the qualities sought for. * * *

The theory of the explosion of the powder may be expreesed in chemical symbols as follows: * * *

The gases formed, as shown by this reaction, are harmless, and those helonging to a perfect detonation. Expcrience hae confirmed this theory.

The old powder has heen in the market some five years. If the operations of the company had not heen crippled during a good part of that time hy a lawsuit, I helieve that its powder would have before this estahlished a wide reputation for safety and reliability. As it is, we have yet to hear of a single human being who has heen injured hy it.

In the new powder, the principle of the old has been preserved. Its general features, as compared with the older powders in the market, are that it containe less nitro-glycerin which is combined with more resilient materials.

A concentration of power is characteristic of high explosives. The denser the powder, other things being equal, the greater this concentration, and the more advantageous its use, since smaller holes will euffice to hold the quantity required for a given work. Though Vigorit is not the densest powder in the market, its safety against tamping admits of its heing thoroughly compacted in the bore-hole, so as to get great concentration.

In concluding his report and summing up his facts, Mr. Quinan says:

I think tnat the powder now made by your company is the hest in the market, because it possesses more of the qualities desirable in a blasting powder than any other. Its characteristics may be summed up as follows:

First—It is one of the strongest, and its strength ie more uniform than any other, from the nature of the absorhents and the thorough incorporation of the ingredients. This can be shown hy successive tests in the pressure gauge. Neither does the strength vary from hygrometric changes of the atmosphere.

Second—It is safe against spontaneoue decomposition. The nitro-glycerin is made from the hest materials, and is thoroughly purified before being put into the powder.

Third—It does not leak. Ie contains less nitro-glycerin, and this is better absorbed than in most powders. It does not lose strength in this way, and there is no exuding nitro-glycerin to render its transportation and handling perilous.

Fourth—It is not deliquescent, and can be used in wet holes as well as dry. It can he stored in damp places without spoiling. It does not undergo sudden changes of character in regard to sensitiveness, leading to accidents in its use.

Fifth—It ie safe against fire, friction, and the shocks and jars of use.

Sixth—It is resilient and elastic, and can be tamped with perfect eafety so as to get any desired degree of condensation in the hore-hole.

Seventh—It loses less in strength from freezing than any other nitro-glycerin powder, hecause it is less dependent upon the nitro-glycerin.

Eighth—It is more efficient than most other powders under slight confinement, because it is susceptible to detonation by the cap.

Ninth—When exploded there is no fine dust or poisonous matter scattered through the atmosphere to be inhaled into the miner's lungs, to his discomfort or detriment,

Tenth—The gases produced hy explosion are innoxious. Most of the visible smoke is condensed aqueous vapor, which requires hut a few moments to dissipate. The poisonous carbonic oxide and irritating, throat-rasping oxides of nitrogen, are avoided by properly proportioning the oxygen to the other chemical elemente, and by making the powder susceptihle to perfect detonation by the cap.

Pleasure in Recommending, Etc.

OAKDALE, Stanislaus Co., Cal., March 6, 1882.

Messrs. Dewey & Co.—DEAR SIRS:—I hereby acknowledge receipt of patent with copies, for which please accept my sincere thanks. I shall take pleasure in recommending your agency when I have an opportunity.

Yours Truly, J. M. NELSON.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send nons but worthy men.

O. W. MCGREW—Santa Clara county.
M. P. OWEN—Santa Cruz county.
B. W. CROWELL, San Benito and Monterey counties.
J. W. A. WRIGHT—Merced, Tulare and Kern counties.
JARED C. HOAG—California.

Sewing Machines.

Several first-class styles, good as new, will be sold at a bargain. Call on or address H. F. D., at this office.

A TURNED LEAF will point out the article supposed to be of special interest to persons receiving sample copies of this paper.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

PERSONS receiving a sample copy of the MINING AND SCIENTIFIC PRESS *with this notice marked*, are requested to examine the merits of the same, and consider fairly its claims for support, and if consistent, subscribe for the paper through the P. M. or agent delivering it, or otherwise. We shall send it, on trial, at the rate of $4 per annum for any period the reader may wish. Please notice our terms elsewhere, and if desired, send for further samples and information. Those who can circulate this No. further to our advantage are invited to do so.

BOUND VOLUMES OF THE PRESS.—We have a few sets of the back files of the MINING AND SCIENTIFIC PRESS which we will sell for $3 per (half-yearly) volume. In cloth and leather binding, $5. These volumes, complete, are scarce and valuable for future reference and library use.

CORRESPONDENCE on mining and other subjects represented by this journal is solicited from all reliable sources. Send us information, early and often, if ever so brief.

BY TELEPHONE.—Subscribers, advertisers and other patrons of this office can address orders, or make appointments with the proprietors or agents by telephone, as we are connected with the central systemin San Francisco.

THE State Mining Bureau, No. 212 Sutter street, is open to the public from 10 o'clock A. M., to 5 o'clock P. M daily, (Sundays excepted). Henry G. Hanks, State Mineralogist.

Cylinder Printing Press for Sale.

"THE $1,000 CHALLENGE"

Ore Feeder for Quartz Mills.

OVER 800 ARE NOW IN USE, GIVING ENTIRE SATISFACTION.

Awarded First Premium at the Tenth and Twelfth Industrial Fairs of the Mechanics' Institute.

Twenty Per Cent. More Ore Crushed with Fifteen Per Cent. Less Wear of Iron than by Hand Feeding.

The accompanying cut illustrates the recently introduced Grip, and also the Spring Attachment, which replaces the Weight heretofore used, and which are obvious improvements.

It is now fully demonstrated, after careful and long continued experimentation and practical use, that the plan upon which a perfect Ore Feeder must be constructed is that of a carrier, and not that of a shaking table. Uniform and accurate feeding is not possible upon the latter plan. The ore must be evenly carried, upon a steadily advancing plane or table, to the line of discharge, and there simply dropped. Jerky or spasmodic contrivances will not answer the purpose for wet or sticky ores

The Challenge Ore Feeders are now in Use in the following Mills, besides many others

Superiority of the "Challenge" Ore Feeder Demonstrated!

At the "Christy" Mill, Uintah County, Utah, the "Eclipse" Feeders, (conceived by E. Coleman) were introduced, but not carrying a regular supply of ore for the crushing capacity of the stamps, were replaced by the "Challenge," which are now running and the stamps crushing forty (40) per cent. more ore than was done by the "Eclipse."

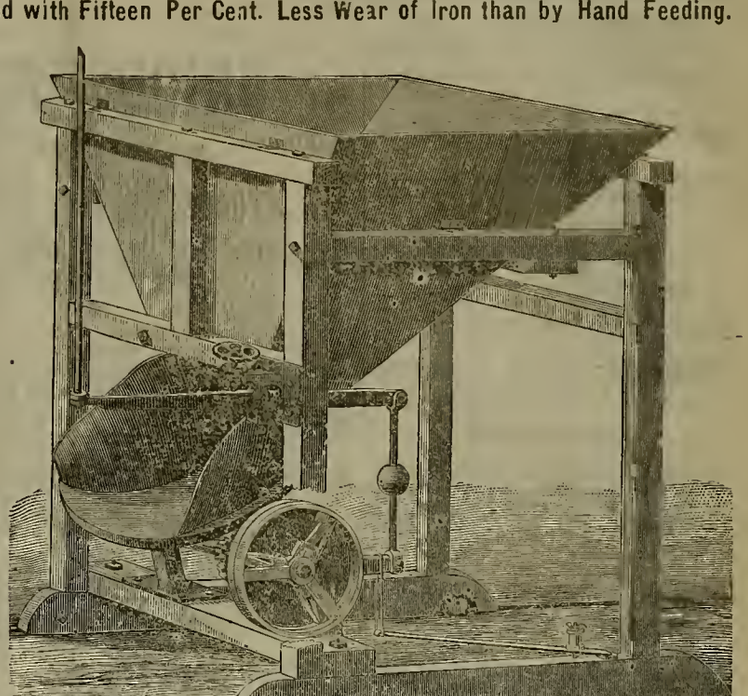
The "Harshaw" or "Hermosa" Mill, of Patagonia District, Arizona, was also originally fitted with "Eclipse" Feeders, but after a few weeks trial they were pronounced inadequate to the work, discarded, and the "Challenge" adopted

The "Silver King," Mill of Arizona, also removed the "Eclipse" Feeders to give place to the "Challenge."

The "Sola" Mill, of Brown's Valley, Yuba County, Cal., was fitted with "Victor" Feeders, manufactured by E. T. Steen, but proving insufficient, the "Challenge" Feeders were substituted.

Four of the "Victor" Feeders, manufactured by E. T. Steen, were also placed in the "Alexander" Mill, at Grantsville, Nevada, but after a fair trial were discarded, and Hendy's Feeders fitted, and four others of the same pattern added when the second twenty stamps were erected.

These cases are simply cited from among many similar instances, in proof of the vast superiority of the "Challenge" Feeders over all others.



JOSHUA HENDY, Agent,

Machine Works, 49 and 51 Fremont Street, San Francisco.

Manufacturer of Quartz, Saw Mill and General Machinery. Also Agent for BAKER ROTARY PRESSURE BLOWERS, and WILBRAHAM ROTARY PISTON PUMPS. P. BLAISDELL & CO.'S Machinists' Tools. HOT POLISHED SHAFTING from the Akron Iron Company, of Akron, Ohio.

Dealer in New and Second Hand Engines, Boilers, and all Descriptions of Machinery.

VIGORIT POWDER.

NO ACCIDENT HAS EVER HAPPENED.

ALL POWDERS manufactured by the California Vigorit Powder Co. are SUBMITTED during the course of manufacture TO SCIENTIFIC and accurate TESTS for safety and strength.

They are tested for Safety against Friction, Fire, a Temperature of 212° Fahr., and the various shocks to which Powder is liable in practical handling.

The following qualities are common to all grades of Powder manufactured by the Company:

Safety; Non-Leakage; Freedom from Noxious Gases; Uniformity and Strength.

If consumers desire it, the EXACT STRENGTH of any Powder shipped to them will be GIVEN IN FOOT POUNDS.

☞Send for Pamphlet showing methods of testing the different qualities of all Powders.

The Company manufactures:

DETONITE.

This is an explosive involving new principles and recently patented. It is the **Strongest Powder ever placed on the Market,** in this country or abroad. It is the **Safest Strong Powder ever made.** For very refractory rock this Powder is the most economical in the market.

VIGORIT. No. 1, XX.

This Powder is **Stronger than the Highest Grades of Hercules or Giant.** It is only surpassed by "Detonite." It is suitable for hard rock.

VIGORIT, No. 1.

For general work this Powder has no superior. It has the advantage over Giant, Hercules or Vulcan in safety and freedom from noxious fumes.

VIGORIT, No. 2.

Equal to any corresponding Grade in the Market.

LOW POWDER.

VIGORIT, L. P.

This is a Powder suitable for **Bank Blasting, Log Splitting** or the work generally in which Black Powder can be used. It is STRONGER THAN BLACK POWDER, having from twice to ten times the effective strength, depending on resistance. It is **Superior to Judson Powder,** in being more sensitive to the cap and more convenient in handling.

Best Qualities of FUSE and CAPS sold at Lowest Rates.

VOLUME XLIV Number 12.

An Electric Light Tower

The accompanying cut represents the electric light tower, 200 ft. higb, erected at the intersection of Santa Clara and Market streets, San Jose, Santa Clara county, in this State. It commences atthe four cornere of the streets with four-inob gas pipe,which eize is used for a distance of 100 ft., then 50 ft. of three-inch, followed by 50 ft. of two-inob, the diagonal and oircular braces being of amaller eized pipe. It has a width of 75 ft. at the base and 4 ft. at the top, and is crowned by a shield wbich acte not only as a protection for tbe lamps, but also serves as a diffuser of light.

There are eix lamps of 4000-candle power each,furnisbed by the California Electric Light Co.,and driven by a No 6 Brush dynamo-electric msobine with an expenditure of nine horse-power. The effect prodnced is very much like brigbt moonligbt, the lights heing so high that none of the direct raye reach the eye. For a distance of half a mile from the tower in all directions the light is brighter than would be prodnced by an ordinary gas lamp every 75 ft., while on the two atreets over which the lights are placed there is sufficient light for ordinary purposes for a distance of two miles.

About a year ago the subject of lighting the streets of cities by meane of powerfnl electric ligbts placed at high altitudes was firet agitated in the East; and a few monthe thereafter a practical test of the matter was made at several points—the most notable one being that of the tower constructed at Akron, Ohio. This was erected from the street, of boiler iron, 207 ft. high, in the form of a mast, 36 inches at the base and 8 incbee at the top. It is held perpendicular hy iron cables in the form of guys, and the lamps are raised and lowered by machinery. In other places experiments were made by placing the ligbt on the spires of public buildings and other high elevations; but to Mr. J. J. Owen, editor and proprietor of the San Jose *Mercury*, belongs the credit of conceiving this the most beautiful, effective and suitable erection for the illumination of a city by the electric light, and the success of the experiment has exceeded the most sanguine expectations of the projector. Some time since the City Council ordered all the gas lampe extinguished, in order that the merits of tbe tower light might he tested. The result was, that one-third of all the gas lamps in the whole city will remain extinguished, the tower light heing adopted in their stead, and it is now running permanently. It was never expected that one tower would light the whole city. At first five or six were thought necessary, bnt it is now decided that four will be all that will be needed, and that number will give a much greater light than could possibly he obtained from other methods of illumination, and the tower system will have the advantage of castiog the light in the snburbs, where no gas lamps were erected, but where the property was taxed for their maintenance.

A company just organized, composed of the leading business men of San Jose, will proceed to erect otber towers to light the whole city, as well as to furnish lights for stores and other large buildings, and San Jose may justly feel proud of heing the first city on the Pacific coast to be lighted by electricity. Regarding its use at Akron, Ohio, we copy below a letter from the President of Akron City Council, J. Park Alexander:

DEAR SIR:—After a six months' trial of the "tower system" for city lighting, I am more than ever impressed with its superior merits and adaptability as a means to light all parts of a city. Our two stations (towers) displaced 325 of our 800 lamps, and have cost us upon an average for all-night lighting less than 60 cents per post per month. The same labor aod steam capacity would run four more stations (towers), and thus reduce the aggregate cost to hut a trifle more for the displacement of 600 or 700 more lampe. A very important feature of the tower system is the fact that it lights up the whole area—alleys, back streets, vacant lots, etc., that with any other system are not lighted, and mnst he the hiding places for thoee of evil intent. In this feature alone, as a governmental aid, it is worthy of mnch commendation.

I am confident that I express the candid judgment of our hest citizens, when I state that, day by day, the opinion hae gained accessions as to thie syetem bere, wbere it bas heen in constant nse since its adoption. The higher the better; not less than 200 ft., and better 500. With either hight, streete within 1,000 ft. of each station receive ahout eqnal benefit, and wben the stations are favorahly situated both sides are equally light from one or the other stations. Foliage is a source of shadows in the tower aystem; but with stations witbin 2,000 or 3,000 ft. of eacb other, the objection is of little weigbt, and is more than compensated by the enjoyable light dnring six or seven montbs of the year when there is no foliage, and that, too, in onr inclement season, when the light is the most acceptable. As a matter of economy, it is the cbeapest of all street lights. It is a bleesing to all alike, rich and poor, and must, when fairly tested, supplant all otber systems now in uee.

THE ELECTRIC LIGHT TOWER, AT SAN JOSE, CAL.

Academy of Sciences.

The regular semi-monthly meeting of the California Academy of Sciences was held on Monday evening last; Vice-Preeident Behr in the cbair.

The following were elected life members: William T. Coleman, Henry T. Scott; reeident member, Arthur A. Smith.

The following were proposed for life membership: Jacob Z. Davis, James H. Goodman, Hermann Schussler, Winfield S. Keyes, John W. Ackerson; for resident membership, Prof. J. J. Rivers, Daniel E. Hayes.

Donatione to the library included a large number of valnable publications and exchanges.

Donations to the museum were received from Dr. Arthur B. Stont—a Gila moneter, or species of large lizard; two horned toads from Arizona, (prepared and mounted); one basket star-fish from the coast of California, and specimens of asbestos from the Tyrol. W. G. W. Harford presented two species of variegated lizards, from the Arizona deeert. Captain R. W. Simpeon, a shark's jaw. J. H. Mahoney, a loaf of bread, made by the Navajo Indians of black corn. Prof. Henry A. Ward, a photograph of the *Elephas Primigenius*, in the Royal Mnseum at Stuttgart. Frank Monk, of Monterey, Cal., presented, through B. B. Redding, a mass of fish eggs on eea-weed. Tbey are from fish of the perch family. A large blackboard drawing was made by Dr. Albert Kellogg, and Mr. Harford called attention to the peculiar glutinous material by which the eggs are attached to the sea-weed, showing it to he a tenacions, transparent and viscid snbstance. The sea-weed wae a species of black *algæ*.

A. W. Jackson, Jr., instructor in Mineralogy at the State University, read a paper on "The General Principles of the Nomenclature of the Massive Crystalline Rocks."

A short paper on the increase of temperature with depth, by Chas. Forman, of Virginia, Nev., was read. This we give in another column.

Dr. H. W. Harkness presented a fine specimen of a new fuogus, allied to the puff-balls, found by Mrs. Dr. Curran near Fort Point, which is the first of this genus ever fonnd on tbis coast, and which he named *Polyposium Curranii*, in honor of the discoverer.

AID FOR BOYS AND GIRLS.—The Boys' and Girls' Aid Society is one of the associations in our midst which is deserving of hearty support, as of a practical character, doing good in a branch too apt to be overlooked. The institution became embarrassed with a debt which a thoughtful and charitable lady of this city, on being informed of the amount. paid off. At a meeting of the society the following resolution was adopted: *Resolved*, That the Secretary is hereby instructed to convey to Mrs. Charles Crocker the thanks of the Trustees of the Boys' and Girls' Aid Society for the liberal gift of $1,352.55, contribnted by her to friends of the society. Coming at the time when it did it has proved especially encouraging. By means of it all debts of the society have heen paid, and the Trustees have been enabled to enter upon the new quarter with confidence that their efforts in behalf of neglected children will meet with support from the public in future.

NINE and a half pounds of rock from the Ford & Mullen mine at Graee Valley eold this week for $589.25.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Montana Mines.

The Mines of Silver Creek Dietiict.

Editors Press:—Montana, as a mining Territory, has had some prominence since 1862. In the early days the gold placers made the world stare, and evsn now, and for many years to come, the placer ground yet unworked will produce millions of dollars worth of dust.

Lode mining is as yet in its infancy in the Territory, there not heing over half a scors of prominsnt quartz camps in the bounds of the 92,000,000 acres of land composing the Territory. However, during ths past year several

New Dietricts Have Been Diecovered

And outside capital has heen sending its experts to examins the merits of our gold, silver and copper mines.

It was not my intention in this letter to speak generally of Montana, but more locally. For many months the fame of the great Drum Lummon—on whoss merits this camp was started—has gone abroad. California capitalists have been hsre and examined the property; also, Eastsrn and foreign, but as yet the great property has not changed hands. Yet it is sincerely hoped that it will in the near future be owned by Californians.

The Drum Lummon is said to bs the

Widest Vein for its Richness

Ever discovered in the world. It shows a width of 80 ft. at 160 ft. depth, the deepest workings. It is said that the entire ledge matter will pay for extraction and milling, and a handsome profit hesides, whils some streaks in the mill, some of ssveral feet in width, go up into the hundreds of dollars psr ton in silver and gold.

Mr. Thos. Cruse, the sole owner, owns 3,000 ft. of this vein. The eastern 1,500 ft. is known as the North Star, but is not much developed. Both the claims are patented.

Mr. Cruse's reduction facilities consist of an antiquated fivs-stamp mill, two pans and a sstler, the ores carrying considerahle carbonate of copper. The process is something like ths Aaron.

Fabulous Stories

Have been told of the yield of this mill during the two years Mr. C. has heen running it, and no one knows to a certainty what it has produced, Mr. Cruss keeping that information strictly to himsslf. That it has paid handsomely no one douhts. Mr. C. began crushing ore ahout two years ago. He had just borrowed $15,000; in sight months the last installment of ths $15,000 was paid, and a handsome surplus in the bank. Since that time considerahls dead work has been done, 10 stamps and a larger engine and hoiler paid for; besides, a considerahle quantity of wood, chemicals and supplies are yet on hand.

This mine could easily and cheaply hs developed by a crosscut tunnel run in from Silver creek. An 800-ft. tunnel would cut the mine ahout 500 ft. in depth, and all the ors could he dnmped in front of the stamps from the mine car, thereby saving the cost of rehandling. In fact, if worked properly the mine is most admirably situated for economical working.

The Section of Country

Within thres miles of the Drum Lummon is slowly hecoming noted for its mineral wealth.

The Gloster, a gold mine, is well developed, has 50 stamps at work, and 30 more, making 80 in all. Will be dropping by April 15th.

The Belmont mine has hesn a steady producer of gold bullion for several years. Has 30 stamps at work. Mr. L. McL. Baldwin, a California gentleman, has heen in charge as superintendent for a fsw months, as the mine was badly managed heretofore. Mr. B. has just got it in shaps for thorough work. The 15th of this month more miners will he put on, and good dividends are expected to he paid, as the mine has vast reserves of rich quartz.

The Bluebird has a 10-stamp mill, and has produced a fortune for each of its owners, Cotter and Hinkey, and has enough in sight to start thsir children in businss.

The Bald Butte mines are owned hy three wealthy gentlemen of Helena. One of the Sharpneck one-stamp mills, made at Blair, Nebraska, has heen at work for several months on this property, and has done excellent work, crushing about six tons of quartz per 24 hours.

The Whippoorwill gold mine has a complete 10-stamp mill, but has not been running this winter, although there is plsnty of quartz in the vicinity to keep many more stamps in opsration.

Ths Penobscot has 40 idle stamps for sale, this mine having ceased to work over a year ago. There are several stories to acconnt for this, and the most likely one is that a ring is trying to get control of the mine, when a new plant will he put up and the concern run on a monsy-making basis, and not so extravagantly as before.

Outside of those mentioned, tbs Silver Creek district has any number of mines in all stages of development, which only require capital to make them famous. This district is in Lewis and Clarks counties, 20 miles northwsst of Helena. The main range of the Rocky monntains lies on tbe west of the district.

Should onr hopes he verified, and Californians purchass ths great Drum Lummon, no douht many California companies would be operating in this section bsfore many months.

Montana has enough Eastern companies. We now need and want ths experienced Western capitalist. R.

Marysvills, Montana, March 7, 1882.

Those "Obstinate" Ores.

Editors Press:—Every little while we see going the rounds of the press articles on the impossihility of extracting the precious metals from the class of ore which they style obstinate.

Now, while I admit there is difficulty in some instances, nnder certain conditions of ore and modes of handling, I deny the main proposition. Gold and silver is in no combination that the skill of this ags cannot release it from its matrix, and I will add further, easily. I defy any man to show ms gold or silver ore from which ths metals cannot he taken, and more espscially gold.

Silver is surrounded by ten-fold more difficulties when all its many possihle combinations are taken into consideration, and yet ths extraction of silver, hy practical modes, is no uncertain question. With hoth metals it is simply a mattsr of expense, profit and loss.

To properly extract the precious metals you must conform to natural demands for overcoming natural difficulties, and to do this requires, often, patient investigation, practical experiencs and mors or less scientific knowledge.

Too large a number of mining investors, I will not say experienced miners, think it only necessary to nut a set of stamps running (if working gold ore), with the addition of pans, if silver ore, and all is done necessary for success. Then if the ore does not pan out nearly up to assay it is "obstinate" or rshellious ors.

Ths trouhle often is not so much in tho ore, as in the error of ths idea, that it must yield to stamps and simple manipulation, and if it does not its obstinacy cannot hs overcome.

I have written more or less on this subject of extraction of the precious metals, and know it is all waste thought, still one would think that the multitude of failures would set sensihle men to studying a little on the various modes of treatment, of ths one hest suited to their especial ores, and believe a littls in the progress of mining as well as in other branchss of industry, before they rest all on simply stamping tbe metal out and, in the end, find stamping has crushed the ore and crushed their enterpriss at the sams time.

What a field of mining knowledge we have before us! I have heen investigating the past; have waded through the mining lore from Abraham's time to the present, and you must appreciate ths prssent knowledge when you seek to find what they knew in past ages. The advance in mining skill in the past 30 years has exceeded that of the past 3,000 years. We then must say there is hut one excuse for half the failures—a lack of study and experience. Men who invest in mining venturss must begin to properly appreciate, and pay for scientific knowledge and practical experience. They should ever hear in mind that they are working for the *precious* metals. Almarin B. Paul.

Robinson Camp, Colorado.

Editors Press:—Robinson Con. Silver Mining Co. is situated on Sheep mountain, Summit county. This famous Robinson mine, from ths first shipment to the present dats, has had her trials and troubles. A few months ago this mine hecame worthless as a dividend-paying mine. Mining experts all the way from New York were numherless, and prononnced it useless. Tbs mine was put under the able management of J. B. Stevens, wbo, heing accustomed to underground mining on the Pacific coast for many years, thoroughly nnderstands mine managsment. To-day Rohinson comes the front with large bodies of high-grade mineral in sight. We notice to-day several assays from the offics, which run 350 ozs. per ton. At present the mine is shipping over the Denver & Rio Grande railroad 15 cars daily to Leadville.

Owing to late developmsnts, with satisfactory results, no doubt Robinson may again stand at the head of the prominent Colorado mines. Ws learn from the Superintendent, Capt. S. Evy, that they will next month ship 20 cars daily over ths Denver & Rio Grande to Lsadville, which will show the good condition of the Robinson mine to the puhlic at largs.

O. M.

Robinson Camp, Colorado, Mar. 10, 1882.

The Alice, Moulton, Lexington and Silver Bow mills and the Bell, Montana and Colorado and Parrot smelters, Montana, are all in smooth and successful operation and are turning ont bullion and matte at a lively rate.

The Ontario mine of Utah has produced hullion valued at $9,356,290.22, and has declared a dividend (No. 76) of 50 cents per share, of $75,000, payahls Feh. 15th; total to date, $4,100,000.

There are nine mills in Galpin county, Colorado. These mills are rnn to their fnll capacity, and carry 447 stamps.

Value of Bars.

Largs hullion scales, and troy weights, ars not always at hand; yet it is oftsn desirable to know the valus of a har hefors sending it from ths works, and as good counter scales, with avoirdupois weights, are generally accessible, the following facts may hs fonnd useful.

The assay value of ons avoirdupois pound of purs silver is $18.85; that of ons avoirdupois ounces is $1.17. The pound of pure gold is worth $301.44, and the ounce $18.84. Hencs it is easy to calculate the value of a har of which the fineness is known, and which has heen weighed on common counter scales to the nearest quarter ounce. For example, a silver har is .969 fine, and weighs 82 lbs. 3¼ ounces.

Then: $18.85 × .969 = $18.26 × 82 = $1,497.32
and 1.17 × .969 = 1.13 × 3¼ = 3.67

Making ths value of the har..... $1,500.99

Each 1-1000th of silver in a har is worth 1.885 cents, and sach 1-1000th of gold 30.14 csnts per avoirdupois pound; thsrefore, if in the above example the bar contained also a littls gold, say .003, and perfect accuracy is not required, it would be sufficient to add to the value 3 times 30.14 cents for each pound weight, or in all $74.14. Again, a gold har is .969 fins and weighs 7 lbs. 13½ oz., or 125½ oz.; then 18.84 × .969 = 18.26 × 125½ = $2,291.63. Or, the value of a gold bar may be calculated as though it were silver, and the result multiplisd by 16.

The commercial or market value is different from the assay value. The discount on silver varies from 10% to 15% of the assay valus, to which is added ¼ of 1% for mintage, or assayer's fee. Gold bars fres from hass metal are subject to a discount or a premium, equal to 1-10 of 1% for every 10 "points," or thousandths, ahove or helow the quoted par finsness; discount if ahove, premium if hslow. The apparent anomaly is due to ths fact that, if there is no hase metal in the har, all that is not gold is silver, whencs, at par finensss, thers is just enough of silver in ths bar to pay parting charges, etc., whils in a finer bar those charges must he met by a discount on the value of the gold. Conversely, a har which is below par fineness commands a premium for the sxtra silver it contains. On account of this arrangement, bars which are more than half gold are stamped with the gold value only, unless they contain much hase metal, when both gold and silver valus is stamped on them. These facts ws take from Aaron's "Leaching of Gold and Silver Ores," for sals by Dewey & Co.

Mixed hars, in which ths gold forms a large part of the valus, but less than half ths weight, are called "dore" hars, and are stamped with the value of hoth the gold and the silver.

Concentrate on One.

There are hundreds of minsrs, all over Arizona, who own from five to a dozen mining locations. To comply with the law aud keep up the yearly assessmsnt work on so many claims, is no easy job for a man who has no other capital than the labor of his hands. If a poor miner should own a dozen claims and desires to keep his title good to all, hs will have to spend $1,200 in work and improvements every year. A miner has got to rustle pretty lively to supply himsslf with grub and clothing and perform the yearly work on so many locations. The fact is, he can't do it, and do justice to himself or fulfill the requirements of the law. The result is that hs keeps himself as poor as the traditional church mouse, and in his efforts to hold on to all his claims, develops none. The little scratching he does yearly on each is of no henefit to the propeity, and in some instances, it might hetter he left undone. We say to our mining friends, this is a policy which will never yield them any substantial results. If you own ten or a dozen claims, select ons or two of ths most promising, and concentrats all your energies in their development. Let the others go. Remember that one good claim is better than a hundred wildcats. If you frittsr away your resources on 10 or 20 prospects, they will always remain prospects, whereas, if you put the work you expsnd on all of them on one, you can hope for some rsward for your time and labor. We know how miners feel ahout parting with a prospect they have held on to, perhaps, for years, hut it is hetter to leave it go than waste many years more in waiting for the capitalist who will never come to purchass it. Devots all your resources to the thorough opening of ons location, then you will discover before the year is out that $1,000 in work and improvements expended on one claim will bs 1,000 times more beneficial to you, financially, than if you had thrown it away on ten. Your purss will he heavier, your heart lighter and you may be in a condition to visit the old folks at home when the A. & P. draws nearer. Try it.—*Arizona Democrat.*

The indications are that there will he a good dsal of prospecting the coming season to the eastward along the route of the Carson and Colorado railroad for deposits of niter, horax and the like.

Dayton prospectors are still moving out to the eastward. Garfield district appears to he their favorits range. Some sxcsllent finds have already heen made.

The bullion product of ths Idaho mine, Grass Valley, for the month of February (four weeks) was $43,000. The usual dividend of $7.50 psr shars, amonnting to $23,250 will be declared.

Open up Your Prospects.

My friend, if you own a mins and want to dispose of it for anything liks a respectable figure, open it up. You may bs as poor as an Arizona editor, but if you havs health and strength, you have the capital which naturs gavs you, and which you can always apply. Don't forget the pertinent fact, that because you have discovered a ledge and snnk a "pot hols" on it, that it is a mins. By no manner of means. Unless it shows extraordinary richness, it is a proposition of very indsfinite value; and even a merchant, looking at the matter from a business point of view, might object to advance a sack of flour and take it as collateral. But if you should use a little muscle and go down 80 or 100 ft., you might strike something that would enahle you to patronize two-hit saloons, go to "Yurrup," and move in ths vsry highest circles for the rest of your days.

Remember that you've got to eat grub while in camp, and a little exercisa polishing ths head of a drill will give you a good appstite. But ahove all things, remember that you can hardly give a prospect away in the Eastern market. If you think you havs got a mine, open it up, and our word for it, if you can show a fair property, with reasonahle development, you will not have to wait long for a huyer.

Therefore, we advise our mining friends to givs up the insane idea which some of them possess of selling their prospects for thousands of dollars. You can't do it; and you might hang on to them until you see the csntury out, before you will find aman who will give you a small fortuns for a coyots hole. We havs had soms experiencs in that line ourselves, and reliable data from ths miuing centers of ths East snahle us to assert as sample facts what we havs written. So, boys, pitch in; develop your mine and muscle at the same time, and in the good days coming, when the "solid man" from the East comes to look at your claim, you can show him a mine and not a gopher hole.—*Arizona Democrat.*

The Arizona *Democrat* says: Inquiries ars coming from everyhody who has a friend and acquaintance in this neighhorhood, and a few words in print will save writiog many letters. We cannot advise miners to come hsre who would arrive here without funds. Almost everything in the mining line is in embroyo here. Thers are no large operations in progress. Only two mills are running in the county. The Tip Top and ths Tuscumhia and other companies are overrun with applications for labor. It is not even a good tims to come hers for prospecting, for all ths high hills and mountain ranges are covered with snow from 2 to 4 ft. deep, and it is csrtain to snow more within the next thirty days, in fact a storm seems to hs commencing as we pen thess lines. Six weeks from to-day, say the 15th or 20th of April, is soon enough for any one to get hsre who wishes to huy mining property, to prospect or to look for work. We helisvs that those who wish to invest in mining can find no better chances than ars presented in Yavapai county, up to a csrtain limit as regards devslopmsnts.

New Mining Region.—The Tucson *Star's* correspondent, who accompanied ths engineers who are running the line of ths Tucson and Gulf of California railroad, writss that the party has run across a wonderful minsral country near and in Myer's district, about 70 miles west of Tucson. The region is unexplored, and is revealing daily vast ledges of mineral of silver and copper. The party have located a large number of claims along the line of their route. Prof. Van Buren, who accompanies ths expedition as mineralogist, says it is the most extraordinary mineral section he has ever seen. The quantity of mineral on the surface is described as wonderful. Ths party will return and make their report about the 15th of next month. Col. Chamhers Scott, assistant of engineers of the Central Pacific railroad, is in charge of the surveying party.

Mining Exhibition at Madrid.—An exhibition of ores, metallurgical processes, etc., is announced to open at Madrid on the 15th of May next. Besides raw materials, such as iron and zinc ore, manufactured products, from a girder to a finished machine, will he admitted. All the ore must be of nativs production, but steam engines from other countriss may be exhibited. The whole process of coal mining will bc shown in operation; and a model of a colliery, with the seams, etc., is to bs constructed. The Rio Tinto mining company will exhihit largely, and the buildings and grounds will be illuminated by electricity. Premiums will he granted to deserving exhihits, and lectures are to hs giveu on mining and metallurgy.

Owing to the fact that great quantities of ice were housed last winter, the Comstock will not make very heavy demands upon the ice companies of the Sierras. Ths Sutro Tunnel company has housed a two years' supply, and the Virginia City and Gold Hill Water company have stored away sufficient to last the leading mines of the Comstock a long tims.

Says the Truckee *Republican:* Judge Keiser has sold the property known as ths old smelting works, a short distance bslow town, to parties who propose purchasing machinery and going into the business of making boxes extensively. The price paid was $750. The same property sold at one time for $28,200.

MECHANICAL PROGRESS.

Malleable Cast Iron.

This term is applied to the product of a special metallurgical operation, which consists in annealing castings in various substances—oxide of iron and lime, for instance. The metal which, before treatment, was hard, brittle, and easily fusible, becomes soft and malleable, capable of being worked by tools, and very difficult to melt. Reaumer was the first to publish an account of this method, although it was probably known before to a few skillful workmen. All classes of cast iron are not equally suitable for this process. Gray and manganesiferous pigs do not give good results; but white and mottled pigs, obtained from very pure ore, are chiefly in request. The process is more easily applied to small objects; and the time of annealing varies, according to size, from two to six days, the temperature of the ovens being 1832° Fahr., corresponding to bright cherry red. Peroxide of iron is about the only substance for cementation now in use. Layers of red hematite, granulated, are placed, between the objects to be annealed, in large pots, luted hermetically and placed on the bottom of the furnace. Care should be taken to allow them to cool completely before leaving the furnace. M. Forquignon has made some researches on the subject, from which he concludes that the softening of the cast iron does not necessarily result from an oxidation of its carbon, but that this oxidation, when it takes place, plays quite a subordinate part. By the action alone of a temperature sufficiently high, but inferior to the point of fusion, the white pig, which is formed by absorption of heat, is destroyed—carbonized, if the expression be permitted. A veritable amorphous graphite, belonging to a special variety, is abundantly deposited throughout the whole mass of the bars, sometimes in the form of small visible agglomerations, and sometimes in a state of dissemination and intimate mixture. Instead of a combination, there is now only a mixture, more or less intimate, more or less homogeneous, of free carbon with free iron, or with a less rich carburet of iron. The pig-iron, deprived of a portion of its combined carbon, is softened, and its resisting properties are modified, chiefly by the change which its structure has undergone.

The operation ends here, if the annealing takes place in an inert substance like coal; if, however, the castings are in contact with a substance capable of burning or absorbing the carbon, a secondary reaction takes place. The free carbon being eliminated from the uppermost layer, the equilibrium determined by the calorific influence is gradually modified; a portion of graphite from the lower layer enters into combination, passes towards the surface, and then disappears, its place being taken by another. The same succession of phenomena is reproduced, until the mean composition of the bar corresponds with the minimum of carburation of the iron in a given case. On the other hand, in an inert medium, the relative quantity of carbon which remains combined is evidently limited by the maximum of carburation, or, in other words, the maximum of solubility of the carbon at the temperature at which the operation takes place.

Such a process recalls, in its general features, that of the cementation of iron; but it is, in principle, more complicated, since it results from the superaccession of two distinct chemical actions. It is easy to understand how this result may be attained by annealings carried to excess in a suitable cement. M. Forquignon does not think that the heat due to the combustion of the free carbon contributes materially to the production of graphite in the oxidizing cements; and annealing with coal would appear to prove that the heat disengaged by the decomposition of the carburet of iron sufficea to explain all. The same disengagement of heat is probably the source from which the carbon draws the energy it requires for combining with the hydrogen and nitrogen.

A proportion of manganese, even less than five-thousandth parts, is sufficient to prevent the softening, which ceases absolutely to be appreciable as soon as the quantity of this metal reaches 2%. As the heat due to the formation of silicate of manganese is very great, it follows that the silicon may, to a certain extent, saturate the manganese and set free the graphite. It should be observed that the castings lose silicon in alkaline cement, in iron filings, and a mixture of sea salt and colcothar, while the lime exerts an oxidizing action. Besides, whatever be the cement employed, the order of the phenomena remains the same; it is only their intensity that varies. Malleable cast iron occupies an intermediate place between steel and gray pig. It differs from the latter by the special nature of its amorphous graphite, as well as by its greater tenacity; and from the former by its slight elongation and its high percentage of graphite. —*London Iron.*

THE OLEANDER POISONOUS.—All parts of the oleander are deadly. A very small quantity of the leaves has been known to kill a horse. The flowers have produced death in those persons who carelessly picked and ate them. The branches, divested of their bark and used as skewers, have poisoned the meat roasted on them, and killed 7 out of 12 persons who partook of it.

A Street Car Improvement.

A street car "man-catcher" has been invented in France, intended to serve for persons falling in front of cars, somewhat as our cow-catchers do for cattle on the track, only the cow-catcher is intended to protect the train, and not the animal, which is usually killed by it as effectually as if it had been run over, while the "man-catcher" is intended to protect the man, and not the car, and therefore contrived to remove the body from before the wheels without seriously injuring it. This contrivance is thus described by the *Railroad Gazette:*

It consists of a plate-iron apron in front of the wheels, with a rigid frame attached, not to the car body, but to the journal boxes, so as to be always the same distance from the rails. This frame carries a plate-iron plow or shoe, the front of which projects in front of each wheel and reaches to within 1½ inches of the rails, and turns aside and away from the car anything that may happen to lie on the rails. The front guard plates are hung on springs, so as to lessen the shock when they strike a body. The apparatus weighs about 100 lbs. per car, and costs (in France) about $9. Experiments made with a manikin presented in all sorts of positions are said to have resulted in throwing it to one side in every case while the car was going at a smart trot. Further than that it is reported that the apparatus was placed on a line in August, 1878, and that since then there have been 14 cases where persons have fallen in front of the cars, and in every instance they have been thrust out of the way of the wheels by the "man-catcher," without serious injury.

The inventor, M. Massilon, has been awarded a gold medal for the device. There is much need of such a device in this city, as the frequent accidents upon our streets fully attest. A single case has cost nearly or quite enough, in the way of damages awarded, to provide the device for an entire road.

MEASURING POWER.—At a recent meeting of the Polytechnic Association of New York city, Mr. John W. Sutton remarked that there were two general systems. One extinguished the power it measured by friction induced for the purpose, and could only be used a short time as a test. The other measured without much retarding, and could in theory be used all the time. The horse-power of engineers' parlance is a little more than an average horse can do steadily ten hours a day. It is thirty-three thousand foot-pounds per minute. It is 550 pounds lifted one foot high each second. On the transmission system, Mr. Sutton's favorite dynamometer was a pulley connected to the shaft by springs with delicate devices for observing while running exactly how far the springs were deflected to know the strain in pounds, which, being multiplied by the velocity in feet per minute, gives the number of foot-pounds per minute. For a crude measurement a belt just able to do the required work without slipping could, with cheap apparatus, be made a test of power. Find by repeated trials just how much strain on a lever of a given length will slip the belt when the machinery is stopped, and we have the strain under which the belt is acting while in use, which, multiplied into the speed, gives the power.

BLUE MILK.—The blue appearance which milk sometimes presents after standing a few days is due to an organism which is allied to bacteria, and can be transplanted into other samples of milk and various solutions. It thrives according to the proportion of acid present and the condition of the casein; it appears after a certain degree of acidification has taken place, and prevents the further formation of acid. The casein must also be unchanged; it is then held in solution during the bluing process. The blueing occurs only in presence of oxygen, and is attended with evolution of carbonic anhydride.—*F. Neelson, in Bied. Centr.*

PECULIAR PHENOMENA.—A writer mentions a peculiarity of newly tempered circular saws, which, when laid down to cool, commence to hum, and if not quickly replaced in the furnace will crack. The humming begins in a low, musical key, and rises in tone until it ends in a snap. The saw does not always crack through from the eye to the perimeter, and it never does so if it is got into the furnace while humming in a low tone. If the crack proceeds but a part of the way, it is from the bottom of a tooth or space and toward the eye. Saw makers do not seem to be able to explain this singular and costly phenomenon.

TO OIL A MILL SPINDLE.—Somebody says: The best way to oil a mill spindle is to guide the oil through a small gas pipe half an inch in diameter, from the outside of the curb down below the burst frame to the bottom of the stone, and thence with an elbow to the bush, upward to a level with the top of the bush. This will thoroughly oil the spindle, and is not a very expensive arrangement.

SHARPENING MILL PICKS.—Emery wheels have been quite extensively used for sharpening millpicks. The best size of wheel for this purpose is said to be eight inches in diameter by one and one-half inches thick. A machine for the purpose of sharpening mill picks, with wheel complete, is in the market and can be purchased for about $30.

SCIENTIFIC PROGRESS.

EXPLOSION OF WATER.—An experiment may easily be made by any person having the means at hand that will illustrate the fact that water practically explodes when relieved with sufficient suddenness of high pressure, while at a temperature due to that pressure, as it is in a steam boiler. Place a piece of dry wood or other not very strong dry porous body inside of a short piece of iron pipe containing water. The pipe, say a short piece of steam pipe, having been fitted for this experiment by attaching to one end a gate valve, with an open way as large, or nearly as large, as the opening in the pipe, and to the other end of the pipe attaching a steam pressure gauge and a safety valve, the whole will be a miniature steam boiler, with water and a pit of wood in it. After fixing the small boiler firmly upon a suitably firm foundation, where steam can be raised, apply heat and raise steam to any desired safe pressure, and maintain it till the porous body in the water becomes thoroughly saturated with the boiler water—a few minutes will suffice; then let the gate valve be opened with a jerk. The instantaneous escape of the steam, followed so closely by the exploded water as to be sensibly simultaneous, may be expected, and the porous bit of wood (which should be of considerable size), if it can be found at all, will be reduced to fine splinters by the expansion, practical explosion, of the water with which its pores have been filled.

A practical application of this experiment is the reduction of wood and other suitable material to fiber preparatory to making your paper pulp. This has been successfully done, but it was found too slow when conducted on a safe scale, and dangerous when done on a commercially economical scale.—*Scientific American.*

KOPLOGRAPHY is the designation given to a new art for which letters patent have recently been taken out by S. K. Devereux, of New Brunswick, N. J. Specimens of this work were exhibited at a late meeting of the polytechnic branch of the American Institute, of New York, by the inventor, who described the process as follows: Cherry, or other tolerably hard wood, is treated on or near the surface with any suitable "filler" and smoothly finished. It is stained preferably a very dark color. Then any designs—preferably hand-made and highly artistic—being drawn or stenciled thereon, the portion of the surface representing these designs is sunk by a rough-pointed instrument, worked by hand with a hammer or by any suitable machinery. The figured portion, with a portion of the adjacent plane surface, is then treated successfully with shellac and gold size, and all which lies on the plane surface is wiped off. When the size is just sufficiently dried, gold-leaf is applied. The gold-leaf is retained on the sized surface only, and is protected by its sunk condition from any wear in the wiping or other treatment of the work. The invention is being tested on some of our standard manufactures of woodwork, including Stevenson's cars and Steinway's pianos. A picture of the landing of the pilgrims is being prepared by this process, on a panel 6½x6 ft., for the steamer *Pilgrim*, being built at Chester.

AN ILLUMINATED BUOY is one of the latest contributions of science to the welfare of man. Imagine an enormous lamp riding the waves. The buoy is a compact wrought-iron vessel, which serves as a receiver of compressed gas. The duration of the flame depends upon the size of the buoy. Some in use in Europe have been made to burn 30 days and some 120 days. It is said that a buoy of sufficient size will contain gas enough to furnish the light for one year. During that time the flame is steady and constant night and day, requiring no attention whatever after once put in operation. The lantern attached to the buoy admits air enough to feed the flame, but not a particle of water can enter. The most violent gales, the greatest force of the waves, submerging even beneath them, has no effect upon this light. It burns with undimmed brightness as long as gas is in its reservoir. The light, it is said, can be thrown six or seven miles in clear weather. Salty deposits are not made on the glass of the lanterns, as has been demonstrated. The refilling of the buoy at certain intervals is performed by a tender, and requires but a few minutes' time. It is done by passing the gas from a storeholder, which contains the gas compressed to ten atmospheres, by means of a flexible tube into the buoy at a pressure of six atmospheres.

NEW APPARATUS FOR THE DETERMINATION OF MELTING POINTS.—The apparatus consists of a small platform of thin ferrotype iron or silver, having an opening for the reception of a thermometer bulb, and a small indentation or depression about 1.5 mm. deep and 2 mm. in diameter. A very small quantity of the substance is melted in the little depression, and while still liquid, a thin platinum wire, bent like an L and fused into a glass float, is immersed in the liquid and held there until the substance solidifies. A thermometer is then inserted in the opening, and the whole apparatus plunged under mercury. The mercury is gently heated and the thermometer carefully watched. As soon as the substance melts, the float rises instantly, and the temperature is noted. Stirring is unnecessary; the whole of the substance is surrounded with mercury, and the attention can be concentrated on the thermometer.

SINGULAR EXPLOSION OF OXYGEN.—M. Sehere, of St. Brienne, has been in the habit of storing his oxygen in a large gas holder of galvanized iron, holding 100 liters and sunk in water. After being about half full for several weeks, he was about to make use of it by carrying a jet of the gas to a flame, with the result of the whole violently exploding. An investigation proved that no carelessness was at the bottom of the matter, the explanation being of a most simple nature, and one that theory would have predicted. A galvanic action had been set up between the iron and the zinc, and hydrogen had been liberated, an explosive mixture of the most powerful character being thus manufactured in the middle of the laboratory. M. Sebere's arm was broken, the place was deluged with water, and considerable further damage resulted. In order to prevent a similar accident, for the future M. Sehere will always keep the interior of his gas-holder well varnished.

THE MOUNT ETNA OBSERVATORY.—The municipality of Catania, in Sicily, has just completed the erection upon Mt. Etna of an observatory at the height of 9,671 ft. above the sea level. It is believed that in the Etna observatory, spectroscopic results will be attained which are impossible at all the previously existing astronomical stations throughout Europe. The site of the observatory has been so selected that, in case of an eruption from the crater, a stream of lava would be divided above the building, and would pass it without injuring it. The structure surrounds an enormous pillar, which supports the great refractor, and the telescope is covered by a movable iron dome. In addition to the telescope, the building is furnished with a collection of meteorological and seismological instruments. From the summit, a lovely view is to be had of the half of Sicily, Malta, the Lipari islands and part of Calabria.

NOVEL REACTIONS OF MILK.—If a little tincture of guaiacum is added to fresh milk, a blue color is produced. Milk heated to 80° or upwards remains uncolored. Sour milk takes the same tint, but the reaction is prevented by the addition of mineral acids and alkalies. If a little starch paste mixed with potassium iodide is added to milk which has been mixed with old oil of turpentine, a fine blue hand appears at the surface of contact and spreads rapidly. Milk freed from albuminous matter does not give this reaction. If to fresh milk there is added first acetic acid to precipitate the caseine, then some caustic potassa, and lastly a trace of a solution of copper sulphate, the violet reaction characteristic of peptone does not appear; but if the milk is allowed to stand 15 to 20 hours before this treatment, the violet color is obtained. Mr. Arnold considers the blue color due to ozone.—*Scientific American.*

SEA WATER ON THE STREETS BAD FOR IRON PIPES.—At the late meeting of the American Institute at New York, Mr. West said salting the streets, or any parts thereof, had been forbidden in many or most cities. In London, it was averred that salting was injurious to the health; he did not know on what grounds. In one of the coast cities of Canada the streets had been sprinkled with sea water, and it was averred by the gas company that the iron pipes in the streets, even far removed from the surface, had been injured by the saturation of the earth with salt.

METEOROLOGICAL RESEARCH.—It is stated that M. Mouchez, Director of the Paris Observatory, is making arrangements for taking meteorological observations at an elevation of 2300 metres by means of a captive balloon. The balloon will be charged with ordinary coal gas. The observations will be specially directed to obtain such data as will facilitate the calculation of atmospheric refraction.

PROF. W. E. AYRTON has invented a sort of web conductor, closely resembling that made by M. Andre. The metal wires form the web of a fabric of which cotton or hemp forms the warp. To secure better insulation, the web may be steeped in melted paraffine, wax or bitumen.

SCIENTIFIC PRIZE OFFER.—A prize of $550 is offered by the Royal Italian Scientific Institution at Venice, for a "statement of the hypothesis recently advanced by physicists on the causes of the phenomena of light, heat, electricity and magnetism."

BY keeping glycerine, castor oil and other viscous liquids in regular motion for some time, Dr. Margatea says, according to *Les Mondes*, that he has obtained a series of characteristic figures.

STEEL BELTS.—A patent recently granted in Vienna and Berlin uses bands of steel, which is tempered and hardened, to transmit motion from one pulley to the other, the faces of the pulleys being turned perfectly flat and then faced with a varnish of resin, shellac and asphalt.

THE Mexican and Ophir mines were each in debt upward of $22,000 on the 1st of March, and assessments are expected.

A NUGGET of gold weighing $130 was found by a Chinaman near Angel's, Calaveras county, one day last week.

The Mining Share Market.

There are no specially enconraging features in the stock market to record. A dispatch from Virginia, dated the 22d, says:

About 250 tons of ore will be extracted from the 2500 level of the Union this week. The ore improves in breasting out upon it. There will be more room for the men next week, and a larger amount of ore will be extracted. The quality of the ore appears to he better as they work hack from the winze. The only place where ore is being extracted at the Mexican is the npraise from the drift on the 2700 level. The west crossent from this drift is still in material giving favorable assays. The joint Union and Sierra Nevada east winze is now almost down to the 2900-ft. level. It will reqnire four or five days to complete the Bullion hulkhead, as it is heing made very strong. The Jacket pump is still pumping, which manages to hold the water. The west cross-cut of Chollar on the 2400 level is showing some quartz ground which is dry. The Alta folks are drilling west from the face of the west drift of the 2150 level to guard against water.

On the 16th orders were issued to cease prospecting on the Yellow Jacket. Since the other companies would not now assist, the Yellow Jacket had nothing else to do bnt to stop. The water continued to rise with the pump rnnning at five strokes, and it wonld have been a nseless expenditure on the part of the Yellow Jacket management to have kept the pumps rnnning. By stopping they save $15,000 per month. They started up again at the instigation of the Bullion company, that company agreeing to pay all the expenses until they can get in their bulkhead on the 2200 level, which has a conecting drift between the Yellow Jacket and Bullion mines.

The joint Union Consolidated and Sierra Nevada east winze is within a few feet of the 2900 level. Another 100 ft. will place the Sierra Nevada and Union on an eqnal footing with the Yellow Jacket as regards depth. The same may be said of the Ophir and Mexican mines. In these north-end mines the sinking has been done in stages, and so gradually that few have thonght much about the great depth that has been attained. The whole series will soon he down to the 3000 level.

The Grass Valley *Union* says: Much of the rich specimen rock taken from the Ford & Mnllen mine is admirably adapted for jewelry, and within the past two weeks 50 lbs. of the rock has been sold to San Francisco lapidaries for $2,600. Some of the rock sold as high as $25 per oz., being more valnable than if it were solid gold.

It has been discovered that the two chief awards made by the Mexican Claims Commission, to the extent of $1,200,000, were obtained by perjury and frand, and the Secretary of State has stopped payment of the installment due at this time.

Improved Quartz Mills.

James Day, of this city, has just patented, through the Mining and Scientific Press Patent Agency, a new form of stamp, the object of which is to increase the force of stroke of the stamp without adding more weight thereto. The mortar, stamp, stem, tappet, arm, etc., are all as usual.

To the top of the frame are holted, or otherwise secured, brackets, to which is bolted a cylinder, in which is a piston. This, which may he an ordinary pump piston, is well packed within the cylinder by cup leather, kept moist and soft by oil or glycerine. The top of the cylinder is open, to expose the top of the piston to the atmosphere. Any other form of piston or packing may be used which is suitable to produce a vacuum within the cylinder.

To the top of the piston or its rod is secured hy a nut a cross-head, projecting on both sides. In its ends are fitted rods or bars, the ends of which are secured. These rods extend downwardly throngh appropriate guide notches or grooves in the cylinder base and brackets, and are provided with a cross-piece, to which their ends are secured hy nuts.

This cross-piece, or follower, is so placed that the the top of the stamp stem, when raised by the cam, will impinge against it and raise it up. In doing this, it raises the piston and creates a vacuum in the cylindcr. When the cam releases the stem, the pressnre of the atmosphere will drive the piston home, and the cross-brace, striking the top of the stem, will give the stamp a momentum much greater than it would have if allowed to fall hy its own weight.

This additional force is a matter of advantage, the inventor claims, because lighter stamps still have as much force in their stroke. The device is intended to be applied to a stamp battery, hut it is obvions that the same principle may he applied to any form of quartz mill whose object is to crush ore hy the action of stamps or heaters. The principle is to provide practical means for increasing the hlow of the heater.

The Bodie *Free Press* says: Davidson & Lockwood, of Sunshine, assisted by Geo. Storrs, an old Comstock expert in the reduction of tailings, have erected near the station a 16-foot water wheel, and put in a large pan for working Bodie slums. Their runs so far have heen satisfactory, and they will add another pan sometime this spring. These gentlemen have already expended hetween $2,000 and $3,000 on this enterprise.

One of the most pressing wants of Tombstone, says the Tombstone *Epitaph*, is reduction works for the treatment of smelting ores. The snpply of this sort of ores in Cochise county is practically unlimited. They are so varied in their character and so rich in the precious metals, independent of the commoner bases of copper and lead, that a system for their treatment cannot prove otherwise than highly remunerative.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

ALPINE.

Bullion.—Monitor *Argus*, March 13: The Isabelle G. and S. M. Co. made two shipments of bullion last week, the first on Tuesday and the secood on Saturday. This speaks louder than words can express for the richneee of the ore in the Stella mine. Mr. Benalloch, a mioing expert from Grass Valley, was up and examined the Stella mine, belonging to the Isabelle G. and S. M. Co. We understand that he was well pleased with the prospects, and thinks the Stella a rich mine.

AMADOR.

Red Bank Gravel.—Amador *Sentinel*, Morch 16: On our return from the marble quarry, the other day, we made a short etop at the Red Bank hydraulic claim, owned and worked by a company compoeed of this following-named geotlemen: H. P. Gordon, J. W. Perry, J. Crane and Wm. Hynde. It is being vigorously worked, and though not yet fully developed, is paying modsrately; 250 inches of water and 650 ft of piping, with a fall of 140 ft pressure, which is forced through a No. 1 Giant nozzle, sweeps everything before it; 140 ft of the flume was cleaned up on the 8th instaot, which, we understend, resulted satisfactorily to the owners. We were informed that the extent of this claim is sufficient to employ the present force ten years to come, as the water supply will not permit of its being worked only about five months in the year.

The quartz in the Pacific mine, one would suppose, is very rich, as the eervices of a watchman is required to prevent the underground employes from carryiog it away in their pockets and dioner buckets.

Walton.—*Ledger*, March 18: This mine, in Hunt's gulch, is being worked with the energy which has characterized the present management. The tunnel is 540 ft, and a crosscut has been run 130 ft, prospecting for the ledge. The ledge has not heen struck, as yet, nor any ore body of any magnitude, except in the shaft, where the quartz is from 3 to 4 ft wide. The crosscut has not reached the point where it is expected to encounter the ledge, though it cannot be far off. The mill is about ready to start up, and there is plenty of rock on the dump to keep its 20 stamps in motion. Tom Earbart is the practical miner in charge of the miuing operatioua.

Gover.—The taking out of water from the shaft is progressing. The mine is pretty well filled with water, and it is thought it will require from two to three months to free it.

Miscellaneous.—For the first time this winter miners are rejoicing in having abundance of water. The liquid element is now ample for all mioing purposes.

Alps.—This quartz claim is located ono mile and o quarter southeast of Jackson. It has lately been purchased by C. Sumner and W. F. Deteret, who have since been quietly proceeding with its development. There is a shait 40 feet deep, with a well-defined quartz ledge, eight feet wide at the bottom. Tbie ledge has been uncovered by an exeavation varyiog from two to ten feet deep for a distaoce of 500 feet. In additioo to thie, above the shaft a hill rises a couple of hundred feet, 150 of which exhibits the quartz body oloug its surface, indicating that the ore reaches 200 feet in depth from the hill summit. As regards the quality of the quartz, it is said to prospect olong its entire length and in payiog quantities. Not a barren spot has been found. It is estimated that it will average from $6 to $8 per ton by mill process, without the sulphurets, of which it contaiue o heavy percentago, the sulphurets carryiog from $120 to $130 per ton in gold.

BUTTE.

Buck's Valley Quartz Mine.—Oroville *Mercury*, March 17: The Buck's Valley quartz lodo, owned by Messrs. Mathews, Pardee & Fitch, has heco bonded to San Francisco parties; terms unknown. This very valuable property has been well opened, and shows a well-defined vein from three to ten ft wide, the average assay being over $20 per ton. It is to be hoped that Buck's valley will soon ring with the music of a 20-stamp mill, and that a new era will be inaugurated in quartz mining in and about Buck's ranch.

CALAVERAS.

Jupiter.—Cor. *Mountain Echo*, March 14: W. A. Keefer, the superintendont of the Jupiter D ep Blue gravel mine at Dogtown, has at last, after an outlay of nearly a hundred thousand dollars, got the mine in operatioo. This is one of the most gigantic hydraulic mining enterprises ever undertaken in this county, and it is due to the skill and enterprising spirit of Mr. Keefer that the people of this section are indebted for whatever benefit may accrue to them through the working of the mine. Further particulars in reference to this mine will be given in future.

Black Oak.—Oehorn & Fisher, proprietors of the celebrated Black Oak mine, are steadily at work developiog their claim. In addition to the nine distinct veins mentioned in a former issue of this paper, aoother one has opened out in close proximity to the others. These ten veins are from two to three inches in width, and are separated by a kind of slate which carries gold in paying quantities. The deepest shaft is only about 30 ft deep, but the deeper down they go the richer the quartz becomes, and the more compact also. It is evident that before the shaft is sunk to any great depth, the small veins will concentrate and form a solid body of ore.

Sold.—Amos Everhart, of this town, recently sold an interest in o quartz mine near Vallecito, for the neat little sum of $2,000.

Notes.—The Potter, or Big mine, is said to be paying well. The lead continues about the same width, which, it will be remembered, has been stated to be 0 or 10 ft Norman Smith, of this town, while out hunting, the other day, picked up a piece of quartz containing about $15. Keyes and John Fletcher, of this place, are about to engage in a mining enterprise of considerable magnitude. They are now making the necessary preparations for opening the old Dickereon gravel mine near Bald Hill. This claim was worked in early days by Charles Dickinson, and it is said that an immense sum of gold was takeo out by him. The shaft io which the present owners intend starting is over 100 ft deep. A large whim for hoisting purposes will be erected. The Matsou Bros. are still eogaged in arostraing ore from the Brunoer mine, near Albany Flat, and the result of their labors, so far, has proved satisfactory. The average yield of the ore near the surface is from $4 to $5 per ton. The lead, if I.ad it cao be called, is simply immense, and nothing more or lese than a mountain of talc. This mine is supposed to be a continuation of the celebrated Dolan lead, and although the ore, so far as tested, is not of a high grade, the extraordinary facilities for working it, and the small outlay required to extract the ore, makes it one of the most valuable mioes in the county. James Matsco, who is a miner of large experience, speaks highly of the mine.

EL DORADO.

Grizzly Flat.—El Dorado county *Republican*, March 16: The Mount Pleasant is running, but not very full-handed; and the hope is not, as yet, realized of the grand boom anticipated when the new works were finished. Mr. J. E. Lyons is still driving ahead on the Driesbach mine, under the management of Mr. A. A. Gigoo, whose energetic work is highly commended, and it is expected to make quite a stir when the lowest level now being ruo for is reached, as all the quartz prospects *big*. Tbe shaft is down 150 ft, and is to be sunk 50 ft deeper.

Argonaut Mine Sold.—John and Thomas Smith, of Greenwood, half owners of the above mine, and holding the other half oo a bond, transferred the same last week to the Aultman M. and M. Co., for the sum of $50,000 cash. We have this information personally from John

Smith, who was in town and made us a pleasant call on Saturday evening. The parties chiefly interested in the new company are understood to be Eastern men, and will commence work upon the mine at once, and push further development as rapidly as possible, having purchased it as an investment, and with the intention of working it for all there is in it. If managed with reasonable economy and intelligence, by the aid of good machinery, and plenty of it, we are confident the purchasers will never regret their investment.

INYO.

THE MODOC.—Inyo *Independent*, March 18: During the past ten days the amount of ore delivered by Robinson's pack train to the Modoc furnaces at Lookout has been as follows: From lead mines, 43 tons of galena; from Black Warrior mine, 22 tons, and from the Modoc mines, 77 tons—making a total of 142 tons delivered so far. The car samples average 73 ounces silver. The Modoc ore is being hauled in carts. During the next week at least 120 tons more will be out and sacked for shipment. Frank Fitzgerald, the lessee, has 27 miners steadily at work, and says that the mines are all looking better at all points.

NEVADA.

GRAVEL IN THE WIND-UP CLAIM.—*Union*, March 17: The Wind-Up Gravel company, a Grass Valley organization, has been engaged for several years in driving a tunnel for a gravel channel, in the vicinity of Quaker Hill, and there is now a prospect that the labors of the company are about to be rewarded, as a letter has been received from the contractor who is at present driving the drift that he has struck a body of gravel 15 inches in depth, that first appeared in the top of the tunnel, but is now at the bottom, and gives every indication of its being the edge of the channel. The gravel at the bottom of the tunnel is blue, and there is a plentiful showing of black sand. The tunnel is now in a distance of nearly 1,050 ft. For some time the work of driving the tunnel has been in 50 ft contracts—the last 50 ft being in fair working ground, but the 50 ft preceding that was through very hard rock, which was to all appearance the vein or backbone that formed the side of the gravel channel. The stockholders feel quite encouraged at this news from the mine, as nothing had been heard in some time, as owing to deep snow and covered-up roads communication has not been regular with the mine during the winter.

AN IMPORTANT ENTERPRISE.—*Transcript*, March 10: The South Yuba M. T. Co. are operating extensively at Hoyt's Crossing, about five miles northwest of this city. A tunnel 14 ft wide and 8 ft high is being run through a point 630 ft wide that causes a big bend in the river. The enterprise was originated by a local company, who ran a tunnel 6x8 ft a distance of 180 ft, but were obliged to abandon the project and sell their interest on account of the heavy expense of penetrating the hill, which is of solid granite, and requires blasting the entire distance. The new company are in with their enlarged tunnel a distance of 35 ft. They are working 14 men, George T. Eager being general manager, with Skiff and William Murchie as foremen. There are four diamond drills and two machines for running them now on the way from the East. As soon as these arrive and are put in, a force of 30 men, divided in three shifts, will be employed, and work pushed with much greater rapidity than heretofore. It will probably take five or six months more to finish the tunnel. From the lower end of the tunnel a flume 30 ft wide, 6 ft high and 2,000 ft long will be built. A sawmill is to be erected in May for getting out the lumber that will be needed in constructing the flume. The sands of the river bed in that locality are believed to be very rich in gold. Some of the biggest hydraulic mines, such as the North Bloomfield, Eureka Lake and Milton, dump into the channel above the location. By diverting the water through the tunnel and flume, the river bed will be drained a distance of 6,200 ft, and can be worked at a nominal expense. The cost of getting ready to begin mining is roughly estimated at $60,000. Under Mr. Emery's economical and judicious management it will probably not exceed that.

PLACER.

THE CONRAD.—Placer *Herald*, March 18: The Conrad mine, on Duncan Hill, which was very thoroughly opened about a year ago by Roberts & Roberts, has been started up again under the superintendency of Mr. Wm. Roberts. Lack of funds compelled a suspension of operations by Roberts & Roberts last spring. They did a great deal of dead work for the sake of having the mine opened in good shape, but about the time they had finished their tunnel and were ready to begin the extraction of ore, some of their men closed down on them, and they were unable to proceed. There are the best of reasons for believing this to be a very good property. It has now started up with a backing, we understand, that insures its thorough working, and we shall not be surprised to learn soon of the realization of very satisfactory results.

SAN BERNARDINO.

MILL.—San Bernardino *Index*, March 18: E. Sommers shipped yesterday to Calico mining district the smokestack and other machinery for his five-stamp mill, which is now being rapidly erected; also a lot of lumber. Twenty-six thousand pounds of machinery are now waiting at the depot for teams to convey it to Calico. Mr. Sommers assures us that the mill will be in running operation by the fifteenth of April. It is the sole property of Mr. Sommers and will do custom work. The mill will be run for the present with only five stamps, but has a capacity for ten. The miners of Calico will hail with joy the speedy completion of the mill.

CALICO.—The S. P. R. R. has three miles of track laid and ten miles graded on the thirty-fifth parallel, from Mohave station to the Needles. At the Needles they will connect with the Atchison & Topeka end, leading from Santa Fe and Albuquerque to that point. The road is being pushed with energy, and the iron horse will probably reach Calico some time in July, which point will be about 480 miles from San Francisco, thus enabling contractors and others who purchase their supplies and machinery in San Francisco to receive them in Calico via this route as cheap, if not cheaper, than by the Los Angeles route. The line will run through near Black's ranch, passing near the Wells, a distance of two miles from Calico mountain, at which point Messrs. Earl & Garnett propose to sink a well and pump the water to the foot of Calico mountain, where a 20 stamp silver mill will be constructed at once by those parties. The mill will contain all the latest and most valuable improvements that can be made useful in such a structure. They expect to start the mill as soon as the first ten stamps are up. By the time the railroad shall have reached that point the mill will be ready to crush and test the different ores of the many rich mines of that section. This mill, when completed, will crush 80 tons of ore per day. The company propose to dry-crush and amalgamate in pans, settlers and mullers. Recently some very high grade ore has been developed in the Oriental mining group under the superintendency of Judge Walsh, which, it will be remembered, was sold by Messrs. Souther & Walsh to the present owners, Earl & Garnett, for $45,000. The ore from the King mine, adjoining this group, has been milled at the Oro Grande Mining Company's mill on the Mojave river, about 40 miles from San Bernardino, and also at San Francisco, milling from $130 to $416 per ton, free silver ore, and works 990 fine.

SIERRA.

WILL RESUME.—Truckee *Republican*, March 15: The Savage placer company will resume work in their mine in Sierra county at the earliest possible moment. They have on hand several thousand dollars' worth of provisions and supplies, and all they are now waiting for is the disappearance of the snow, or rather its melting away till there is no longer any fear of dangerous slides. The mine is situated about eight miles west of Webber lake, near the old Henness Pass road.

SISKIYOU.

NOTES.—Yreka *Journal*: The Yreka creek mining company's hydraulic elevator has been in operation occasionally this week, but the cold weather has choked up the water supply by frost, so that not more than 30 hours' run can be made at any one time. The Lime Oulch company expect to be at work taking out pay gravel in less than three weeks, the men being now busy at work getting the pumps and derrick wheels ready. By using Lime gulch water for the sluices, the company can take their time getting the dip wheel ready. The cribs are all right, and can be used again for the wheels. At the Centennial, Kanaka and other claims in the Klamath river, the cribs and head dams have not been damaged to any great extent by the recent freshet, as it was only of a few hours' duration, the river receding very rapidly, and it is now down to low-water mark again. The Centennial company intend reopening their claim in Klamath river at the earliest time possible, and preparations are already in progress. Their pit has been filled up completely with tailings from claims above, which will make the work slower in reopening, on account of being unable to cave the banks at start. Their old cribs are all right, and can be used to start an extension wingdam up the river to uncover new ground. Other companies are also getting ready, and expect to take out gold from the deepest claims before the 1st of June.

TRINITY.

WARD.—Trinity *Journal* March 18: O. M. Loveridge, superintendent at the Ward mine, on Oregon Gulch mountain, informs us that good work is being done in the mine this season, and that the ground shows as rich prospects as ever. We look for a good yield from this mine.

WILL COMPLETE.—John Whitmore will resume work on his new hall at once and push it to completion. He this week received a quantity of material for interior finish and decoration from San Francisco. When finished, this will be one of the largest and finest halls in northern California.

MR. JOHN YULE, superintendent of the Lewiston Co.'s mines, was in town this week and gave us a call. We are pleased to learn that the hydraulic elevator is doing even more than was expected of it, and that the ground now being worked prospects well. Mr. Yule anticipates a large clean-up in about a month.

ALL the hydraulic mines in Weaver Basin are now running on full time and with plenty of water. Indications are now more than ever favorable for an average season's run.

INDIAN CREEK.—During the last few storms there has been sufficient rainfall for the miners to get enough water to commence sluicing. Mr. J. A. Johnson is running his hydraulic claim of late; he uses about 2,000 miners' inches of water and this with 200 ft pressure causes debris to travel down Indian creek at a rapid rate. This mine is worked very successfully under the management of James Bowie, who is a thorough, practical, hydraulic miner. Mr. C. A. Sorr, of Igo, Shasta county, made us a short visit a few days since; from him we learn that he has one of his rotary pumps in operation on North Fork of Cottonwood creek, and that it works very satisfactory. The use of this pump, which can be run either by steam or water power, is for raising water on elevations that cannot be supplied with water by means of ditches; and also for working low bars that cannot be drained otherwise than by the use of a pump; and says that the expense of mining in this way is very small compared with digging long ditches. On Tuesday, 28th ult., about 10 A. M., Martin O'Keefe while working his claim, on Spring gulch, was thrown from a bank 20 ft high on to the rocks below and badly bruised, by the ground giving way beneath his feet.

NEVADA.

WASHOE DISTRICT.

SIERRA NEVADA.—*Enterprise*, March 20: On the 2500 level the winze in east crosscut No. 2 has been sunk and timbered 10 ft. North drift No. 2 has been extended 20 ft, and east crosscut No. 5 has been advanced 6 ft. The main north lateral drift has been advanced 32 ft. On the 2700 level No. 2 drift hole has been extended 175 ft, and the joint Union Con. east winze has been sunk 10 ft.

UNION CON.—On the 2700 level east crosscut No. 1 has been extended 27 ft. In the main lateral drift have completed timbering up and cutting out drain. On the 2500 level are preparing to stope out ore. During the week 163 tons and 1060 lbs of ore have been extracted from the 2500 level.

YELLOW JACKET.—Since last weekly report the water in mine has reached a point 107 ft above the 2300 level station. The pumps were stopped on the 16th inst, but were started again yesterday afternoon at the request of the Bullion M. Co., that company agreeing to pay the cost of running the same until they complete a dam they are employed building on the 2200 level of their mine. Since starting the pumps again the water has remained at the same level.

CALIFORNIA.—On the 1650 and 1750 levels are still cleaning out and repairing drifts and winzes connecting with the old Con. Virginia shaft. On the 2700 level are timbering up the joint C. & C. drift.

CON. VIRGINIA.—A small force is still employed in cleaning out and repairing the drifts and winzes on the 1650 and 1750 levels which connect with the old Con. Virginia shaft. On the 2500 level are cleaning out south drift No. 2 preparatory to resuming work.

OPHIR.—On the 2900 level the main south drift has been advanced 13 ft, and is now being timbered up. Are repairing the main incline and the joint California east crosscut on the 1700 level.

MEXICAN.—On the 2700 level the main north lateral drift has been extended 28 ft. In the main south lateral drift have completed the drain and the work of cleaning up. On the 2900 level the main north lateral drift has been extended 25 ft. During the week 45 tons and 1800 lbs of ore have been extracted from the 2700 level.

BULLION DISTRICT.

STOPING.—Lewis *Herald*, March 15: From Mr. James Lovey, the foreman and part owner of the Lady of the Lake mine, in Bullion district, we learn that a force of men are at work stoping out ore. A tunnel will be run on the ledge from the lowest available point, and the mine opened up right away. The company are negotiating for the Nutmeg mill, situated on Indian creek, and distant about 3 miles from the mine. As soon as arrangements are completed the mill will undergo a thorough overhauling and the ore from the mine will be worked. Considerable ore from this mine has been reduced at Salt Lake and Eureka and proved rich, some working as high as $900 per ton. The Nutmeg company have let a contract to J. C. Latta to run a tunnel 100 ft on one of their claims in Campbell district, and if the prospects justify they will do considerable work during the coming summer.

CHERRY CREEK DISTRICT.

A NEW BONANZA IN THE STAR.—White Pine *News*, March 18: We learn that an important strike has been made on the 270 level of the Star this week. The ore there discovered is said to be the richest ever found in the mine. The extent of the new find is not yet fully determined, but it is believed to be a good-sized body, as a large amount of virgin ground, thought to be rich in mineral, lies in the direction where the discovery was made. We are also informed that the water in the shaft which has given so much trouble of late is now fully under control. The pump recently got from the Egan Co. is now at work and handles the water very effectively. A wonderful mine is the Star. In the past three years it has produced over a million dollars, all of which came from the grass roots. If its owners possessed either energy or enterprise, and opened it out as they should have done, it would to-day stand second to no mine in the State. We have been shown a sample of the ore from the new find. It assays $300, and our informant says the ledge, which is 3 ft wide, has been penetrated 60 ft, all the way in the same kind of ore, and at present it is unknown how much further it extends. This is glorious news for the Star people, as well as the residents of this town.

COLUMBUS DISTRICT.

NORTHERN BELLE.—*True Fissure*, March 18: The sinking of the main shaft has reached a depth of 100 ft below the fourth level. At this point a station will be put in, on which the work is now being done. The daily output of ore has been about 53 tons. Both mills are running as usual and are doing the regular amount of work. Shipments of bullion for the week ending March 16th amounted to $14,663.43; the total on March account to that date being $29,480.28.

MOUNT DIABLO.—The stopes from the east and west drifts on the third level are looking well. The stope on the second level, near the center of the mine, continues to open well and shows a body of very fine ore. The mine as a whole is looking very well indeed. Shipments were made on the 11th and 14th inst., amounting to $8,018.72 and $6,272.96 respectively.

GENERAL JACKSON.—This property is still producing ore of a very good grade, the ledge yielding about a ton a day to the man. As soon as a further development is made more men will be put at work.

EAST MOUNT DIABLO.—The drift from the Mount Diablo shaft into the ground of this company is going ahead rapidly and has attained a length of 54 ft. Good progress has been made so far, the ground being of a character that breaks well. Everything is looking favorable.

CORTEZ DISTRICT.

LOOKING WELL.—Cor. Lewis *Herald*, March 15: The mines of this district are looking very well at present. At the Garrison, owned by S. Wenban, they are taking out the usual quantity of high-grade ore, and keeping the 10-stamp mill running steadily. They have not shut down since a year ago last November, only for the necessary clean-ups and repairs. At present writing there is a good showing of rich ore in both inclines, and a large body of a lower grade in the upraise, which will not probably average much over $100 per ton, but what it lacks in quality it will make up in quantity. Griswold & Walsh have a lease on the old workings of the Garrison and are taking out some very rich ore. They have made one shipment of first-class ore and have several tons of second-class on the dump, which they expect will go $200. John Ralls and his partner have lately made a rich strike on a mine they have leased from H. Hughes, situated on Bullion hill. Another valuable mine owned by Hughes, and adjoining the above, is lying idle this winter, as his health is too poor to work it. I understand some Mexicans prospecting at Granite Springs have also found rich ore. S. F. Griswold has resigned the superintendency of the Garrison mine, and D. C. Lane has been appointed to fill the vacancy. S. Wenban has lately put in an air compressor and two Richmond drills, and is working the mine with compressed air instead of Cbinamen. Some difficulty was experienced with the drills at first and break-downs were of common occurrence, but now they are running all right and give good satisfaction.

GARFIELD DISTRICT.

IN LUCK.—Candelaria *True Fissure*, March 18: A very rich prospect was uncovered at the new camp west of McDonald's, in Garfield district. George Box and his partners have developed their location only about 0 ft in length and 3 ft in depth, but have found ore assaying $3,800 per ton. This is excellent encouragement to continue the work.

GOLD PARK DISTRICT.

MILL.—Grantsville *Bonanza*, March 11: Supt. M. San Pedro came in from Gold Park, on Wednesday, and returned on Thursday. He reports everything moving steadily at the Park. The mill works like a charm and the mines continue to improve as work progresses. Work progresses as usual in the mines at Gold Park with the most encouraging results. In the course of a few days an important connection will be made in the Star of the West which will very much facilitate the working of the mine. The mill runs along nicely and does good work; as soon as the weather becomes warmer the other 5 stamps will be dropped which will greatly increase the bullion output. The first shipment of gold from this mill was valued at $3,760.

LEWIS DISTRICT.

OUTLOOK.—Lewis *Herald*, March 15: The mining outlook for the week past has been rather gloomy, owing to the shutting down of the Highland Chief mine, and work temporarily suspended in other mines, though we hear that work will be resumed shortly with the exception of the Highland Chief mine.

STARR-GROVE.—The south drift from the 300 level has been extended 14 ft during the week—total distance in, 32 ft. The ledge is large, with bunches of rich ore scattered through it, with a slight improvement from last accounts.

CHLORIDE.—The main tunnel on the Chloride mine is now in 530 ft with no change in the character of the ledge. The walls are well defined and the flow of water is increasing.

SUN BEAM.—The winze from the lower level of the Sun Beam has reached a depth of 77 ft, and the ore carries considerable black sulphurets. Last reports from the mine are to the effect that the ore is increasing in richness as greater depth is attained.

MORNING STAR.—No work has been done on the Morning Star with the exception of some timbering, as the force are employed in sacking ore and keeping the trails cleared of snow. The ore is packed on mules from the mine to the forks of Lewis canyon, and owing to the late storms is necessarily a slow process.

BETTY O'NEAL.—The stopes in the Betty O'Neal are still yielding the usual quota of ore, and from all appearances will continue to do so for some time to come. The south drift from the lower level still improves and some very rich ore is being extracted therefrom.

ARIZONA.

TYNDAL DISTRICT.—*Citizen*, March 14: Messrs. J. B. Oregg and Frank Cazy came in from Tyndal district last evening. They brought in specimens of spleudid looking ore from the Laura mine, now being opened by the Surprise M. Co., a portion of which will be subjected to a mill test in San Francisco. The Laura shows an immense ledge, with fully 3 ft of high grade, free milling ore. No crosscutting has been done, and the width of the ore body is yet undetermined, but the mine is evidently a very extensive one.

ST. LOUIS CO.—The incorporation of the Oro Plata, Third Term and Florida mines, for $5,000,000, has recently been completed at St. Louis, Mo., with Mr. James Edwards and Geo. S. Foster, of that city, and David Armstrong, of Tucson, as the leading stockholders. Mr. Armstrong will act as superintendent, and expects to commence active operations on the property in a short time.

PIONEER.—Arizona *Democrat*, March 15: There are at present about 150 men employed in Pioneer camp, in the various mines, mostly upon the South Pioneer and its road building. This mine is improving with every day's development. The drift from working shaft is in 110 ft, placing the face 10 ft beyond the former workings and 50 ft underneath, developing an ore body wider, richer, more uniform, and with every evidence of permanency. It is stated that several old miners on the Silver King, familiar with all its inns and outs, unhesitatingly say that the King is the only mine which can compare with the South Pioneer. The drift alluded to will be run 225 ft to the northeast corner of the mine, and is expected to control all of the surface water. At present this drift is draining the former working from 18 to 20 inches daily, and the pump handles the balance in every 4 hours out of 24. From the drift has been already placed on the dump 150 tons of ore, very rich.

MONTANA.

CONCENTRATOR.—*Inter-Mountain*, March 14: A 50-ton concentrator is soon to be erected to treat the ore from the Shakespeare Parrot, a copper property in which very important developments have recently been made, and which is now shipping considerable ore. It is under lease to John Longmaid & Co.

MOULTON.—Everything is running smoothly at the Moulton, though much trouble has been experienced with the mill boilers, which were riveted in a most unworkmanlike manner, reflecting anything but credit on the party or parties who furnished them. At an expense, however, of $500 they have been thoroughly repaired, and are now as good as they should have been when new. They were manufactured by Griffith & Wedge.

BELL.—In the 200 level of the Bell yesterday morning an upraise disclosed a body of ore which developed a width of 4 ft. It samples over 40% copper, and is literally white with native silver. The strike is a rich and important one, and will add still more to the increasing productive capacity of the Bell. The Bell smelter is booming along in good shape, and the stopes in the 200 and 300 levels of the mine are daily increasing in productive capacity.

THE incline shaft on the Shonbar, on which sinking has been lately resumed, is producing good ore. A few thousand dollars expended in development will show the mine to be one of the richest in the district.

PROSPECTORS are already starting out on their hunt for precious metals. Every day, now, since there has been a crust, little squads of 2, 3 and 4 men, drawing a handsled loaded with tools and provisions, may be seen leaving town for the hills. The main tunnel being driven in the Eureka mine, to connect with the Idahoan workings, is in about 500 ft, the breast being in tolerably hard ground.

NEW MEXICO.

THE SHARESPEARE SMELTER.—*New Southwest*, March 11: The lead furnace at Shakespeare has now been running successfully for a period of 2 weeks, and, in that short time, has produced about $60,000 worth of lead and silver bullion. They shut down this week for the lack of iron ore. The company proposes immediately to erect roasting furnaces, where all classes of ores can be treated. This company expects to purchase from miners such ores as it would not pay for the latter to mill, but which, by smelting, will yield them a profit of $3 to $5 per ton. The smelter is now under the superintendence of Messrs. Hiertz & Oruebling, both experienced smelters from the Kansas City smelting and refining works. The owners of the furnace are prepared to treat all ores that are brought to them.

THE SUPERIOR MINE.—The Superior mine, at Shakespeare, which I. N. Cohen, of this town, sold to Jamee E. Carroll, and of which Mr. Carroll sold a one-half interest to an Eastern company, is being steadily developed. The main shaft on the hill is 182 ft in depth, by actual measurement. This shaft is tapped or intersected by a tunnel at the bottom of the hill, which is 232 ft long. It is on the ledge and shows copper all the way. The ore, as all our readers know who are familiar with this mine, is copper, carrying small quantities of silver and gold, but in bunches that are very rich, which, however, it would not pay to work. There are about 1,000 tons of ore on the dump and at the smelter—300 tons being on an average of from 15% to 20% carbonates and oxides. The copper furnace is ready to run, and Mr. Carroll informs us that the only thing lacking is iron ore for a flux. At this writing he is in town, and, after an inspection, thinks he has found, in the neighborhood of Silver City, the quality of finxing ores he requires. The capacity of the copper furnace is 30 tons, and is controlled and run by the same company that runs the lead smelter. This company will do something generally smelting for customers.

THE Silver King, in the Bullard's Peak district, a claim bought by Mr. Henderson from Black & Sullivan, is developing beyond expectations. Two prospect shafts are being sunk, one down 15 and the other 10 ft. In the latter a vein of ore has been followed down that will assay from $500 to $10,000. This vein is improving as it goes down. The other shaft has a vein 2½ to 3 ft of fair milling ore. Out of the 10-ft shaft fully 6 tons of rich ore have been taken this week.

THE force on the Sherman mine is being gradually increased as openings are made where miners can work to advantage. The superintendent informs us that he is now sinking a new main working shaft. The ore body looks splendidly.

IDAHO.

SAWTOOTH.—Yankee Fork *Herald*, March 10: W. H. Casto and Tim Cooper are in from Vienna, Sawtooth district. They report everything in the mining line looking favorable, and predict a big boom in that section early in the season. The Mountain King M. Co. has purchased the machinery for a 20-stamp mill, which will be in as early as June. Grading on the mill site will commence soon as the weather will permit. There are about 25 buildings completed in Vienna. Mr. Mulock came in from Stanley Basin with Messrs. Casto and Cooper. The journey was made on snow shoes. The days are quite warm and the snow settling. The nights, however, are a little chilly. One night this week the thermometer registered 10° below zero.

STRIKE.—Idaho *World*, March 15: Craig Baird tells us that the strike made in Berry's location, about 6 miles southeast of Squaw creek, is as good as was first reported. The vein contains both gold and silver, the latter predominating. Work was suspended some time ago on account of the difficulty of getting timbers to the mine, the snow being about 2 ft deep. Craig advises prospectors not to make a break for that district before April.

SIX men are at work in the Belshazzar mine, on Canyon creek. Eight hundred tons of ore have been taken out during the winter. The rock, which is mostly decomposed, will be put through sluices. Ore is being extracted at the depth of 140 ft from the surface. The ledge is all the way from 3 ft to 10 ft wide. The ore averages well. It is fair milling rock from wall to wall.

THE Sub Rosa tunnel—the lower one—has been driven in 55 ft past the small vein that was tapped a few weeks ago. It is now in very hard rock, which is believed to be the casing of the main ore.

OREGON.

SQUAW LAKE.—Jacksonville *Times*, March 17: Henry Klippel, Esq., returned from the Squaw Lake Ditch Co.'s mines this week. He informs us that the reservoir is now being completed and the ditch cleaned out, preparatory to earnest operations. We expect to hear of some good clean-ups there this year.

CLEAN-UP.—Chas. E. Chappel & Co., of Star gulch, made a clean-up last week, realizing 31 ounces of dust, which is considered flattering under the circumstances. The "giant" became displaced just before starting in, or the showing would be still better.

WATER.—Piping continues at the Sterling mine with a fair supply of water. The weather has been so cold high up in the mountains that very little snow is melting, and the ditch is consequently not full. This company will be able to run until late in the summer, as there is much more snow than usual.

SNOW.—The occasional showers of the past week have been very beneficial to miners, and, if they continue a while longer, a large amount of the glittering dust will be unearthed in spite of the unfavorable winter, for the miners are not losing an available moment. The deep snow in the mountains will also be of great advantage.

WORK has been suspended on the diggings of Bybee, Newman & Hawkett, near Waldo, owing to some misunderstanding, though the ditch is also broken. Excellent reports were expected from there, as the ground is good.

WE LEARN that Logg & McDonnell have suspended operations at their mines on Jackass creek, claiming that they are disturbed by an unusual amount of tailings coming down that stream this season.

UTAH.

CARBONATE.—*Southern Utah Times*, March 4: The Carbonate mine, at a depth of 525 ft, looks better than ever. At the bottom there is a large, fine body of ore, and in quality a great improvement on that found in the upper levels. Competent judges estimate that there is ore enough in sight to keep the smelter running 2 years. If this mine, which is clearly demonstrated to be a true fissure, does not loom up as a rival of the great Ontario, we are much mistaken. Work is being developed on the Charlotte mine with flattering prospects. The ore looks well and it is expected that it will carry silver soon.

FRISCO.—The signs of the times indicate a mining boom for Frisco in the near future, which for generality, extent and grand results, will eclipse anything of the kind that has ever taken place in Southern Utah. It is evident to the most casual observer that the end of the long lane of disappointment is now in sight. The great Pilgrim mining claim has at last brought to light the long sought for mother vein of San Francisco mining district.

Pocket Mining and Nuggets.

Under these headings may be embraced those erratic occurrences of gold which are a mystery to the miner and prospector and a puzzle to the scientist. The finding of nuggets in alluvial places is no uncommon occurrence. Such nuggets vary in weight from half an ounce to many ounces, and are usually worn smooth from water action and the attrition of the rocks of the stream in whose current they have been carried. Usually they bear traces of the quartz, which was their original matrix, and sometimes they consist of nearly one-half quartz, thereby denoting their origin, and, by inference, the origin of all gold found in a natural state. It is proposed, however, to notice here only the occurrence of free gold in veins.

Gold found in its native state in the mines of California is always in the form of an alloy containing some silver. Its specific gravity ranges from 13 to 19½ and its fineness from 600 to 950. The average value is usually a little more than $16 per ounce, which corresponds to 800 in 1,000 parts. As an ore it is found combined with iron sulphides and with tellurium, in the former mechanically and in the latter it is believed chemically, though there are strong reasons to doubt the latter theory. That gold primarily existed in a matrix of quartz scarcely admits of a doubt, but it is also true that it exists in rocks other than quartzose—such as in talcose slate and in iron sulphides permeating slates and schists. In the former case it seems to be the result of mechanical deposition after removal from its home in the silicious rocks; in the latter case it exists in such small quantities as to be appreciable only by fire assay, but not in sufficient quantity to prove profitable for extraction.

There is no example in California of a mine successfully and continuously working gold-bearing rocks which are not quartzose in their nature. The so-called porphyry belts in El Dorado county are merely fissures filled with rotten and decomposed rocks, into which the gold has been mechanically deposited.

Prof. Joseph Leconte, the eminent California geologist, holds that all metalliferous veins have been deposited from hot alkaline waters, circulating through fissures, and that in the case of auriferous veins the solvent of the gold was sulphate of iron, and the sulphate was deoxydized by organic matter in the same solution, the gold and the iron crystallizing at the same moment, one as metal the other as sulphide, so that, although gold exists in the iron sulphide of the unchanged vein only in minute and sometimes microscopic crystals and threads, it occurs in the decomposed portion of the vein, above water-level, in visible particles and often in nuggets; hence, he infers that the larger aggregations result from the coalescence of the minute particles originally contained in a mass of sulphides. In support of this theory it may be stated that the occurrence of free gold in the veins of California diminishes in depth and that the deepest mines are the poorest in specimens or pockets; the Idaho, or Grass Valley, now worked to a depth of 1,000 ft., and yielding about $500,000 per annum, having produced less than $100 per annum in specimens for several years past.

There are two varieties of the telluric ores known to mineralogists, the sylvanite or combination of gold with silver, and the nagyagite or combination with lead, silver, and copper. The former exists abundantly in Calaveras county, in the vicinity of Carson hill, and in Sierra county, between the north and south forks of the Yuba river. In the former locality it occurs in slate rocks, and in the latter at the junction of slate and serpentine. Nagyagite is not known to exist "in place" in California, though samples have been obtained of this ore, but it has been impossible to trace them to a ledge formation.

The ledges carrying sylvanite in both the above-mentioned localities seem to be favorable to the aggregation of large masses of native gold in proximity to the telluridcs. At the Morgan mine, on Carson hill, $110,000 was thrown out at one blast. The gold held the quartz together in ribbons, and cold chisels were used for its extraction. Residents estimate that the mine yielded $2,800,000 in the years 1850 and 1851, and since that period the discovery of pockets has been of annual occurrence in this formation.

The telluride veins of Sierra county, extending from Minnesota to the South Yuba, have also been prolific of pockets or aggregations of gold. The Fellows mine on this belt yielded $250,000 from this source, although the telluric ores were not successfully worked by any process.

Aside from the telluride veins the most notable pocket localities have been in the vicinity of Grass Valley, Nevada county; Auburn, Placer county; and Sonora, Tuolumne county. In all these localities the occurrence of pockets has been in quartz rock running in veins through metamorphic slates, and in almost every instance the discovery of the pockets was the result of accident or chance, though they are sometimes systematically sought by the prospector, who, however, in this class of mining has no better theory than that expressed by Job in Holy Writ, "Surely there is a vein for the silver and a place for the gold where they find it."

It is a singular fact that the native gold so liberally diffused in the quartz should be confined to nests or pockets of limited extent, but of great richness. The continuity of the pocket deposits in depth has been disproved wherever they have been sought; in fact, in most cases, native gold seems to have its origin in gash or surface veins, rather than in true fissures. Near Auburn, in Placer county, the "Green Emigrant" was discovered by chance within 100 ft. of a road traveled for 20 years. The discoverer was an emigrant who had never seen a mine. The gold occurred in its metallic condition, associated with rotten quartz in a slate formation. It was readily extracted by pan and hand mortar. After yielding about $160,000 a mill was erected, but no more pay rock was found.

The "Reece pocket" of Grass Valley contained $40,000, and was worked out in less than a month by hand mortar. Another famous pocket in that district was discovered by a casual visitor who was there in search of health, and who had never seen gold in any other form than the coin of the commonwealth. This yielded $60,000, when all traces of the precious metal were lost, though much money and labor were devoted to further search. In one instance a smooth nugget containing $640 in gold was picked up in a garden path used for many years by the occupant of the premises. There was no ledge in the vicinity. This piece was about half gold and half quartz.

Both the above-named districts, however, contain mines of permanence, where the pay has been regular and steady in true fissure veins of 1,000 ft. in depth, which are still yielding.

Sonora, in Tuolumne county, is another famous pocket locality. Bald mountain, near that place, is a hill of talcose slate permeated with narrow seams of quartz in which pockets varying from $10,000 to $40,000 have been found for many years past. They are soon worked out and others sought. The most celebrated pocket mine of the present time is the "Devol" mine of Sonora, situated only a few feet from the main street of the town. The company, consisting of three partners, took out over $200,000 during the last year without works or

A GOOD PROSPECT—"A NUGGET."

mill. Half of this amount was taken out in a period of three weeks. The veins are narrow and the gold of erratic occurrence in nests and benches. This company is still prosecuting its search, but in more systematic manner, by deep sinking.

Pocket mining continues to be an element in the production of the precious metals, and doubtless many pockets as rich as those discovered await the miner's pick and shovel. The business is precarious, but it has a strange fascination incident to its uncertainty and the sudden reward attending success. The pocket miner's "outfit" is simple and inexpensive. It consists only of a few days' rations of "grub," and pick, pan, and shovel. With these the prospector enters on his campaign and returns to headquarters only when his provisions are exhausted. The most favorable time for his search is after a rain-storm, as the surface is cleared and the rock exposed. Every crevice presenting quartz indications is panned, and when colors are found a trench is run, following the vein, and sinking prosecuted wherever the vein shows richest in gold. Where the metal is much diffused a Mexican arastra is erected on some convenient stream and the decomposed quartz and slate wheeled to the arastra, which usually runs by water power, and though slow in action is very effective as a saver of gold.

The suction fans, now in use on the Comstock—one at the Bonner, one at the old Consolidated Virginia, and a third at the Sierra Nevada shaft—are proving very valuable aids in ventilating the lower levels.

A site has been selected in the upper part of Missoula gulch, Montana, for the erection of the second 40-stamp mill of the Lexington company.

John T. Bradley, of Carson, recently sold two mines in Santa Fe district, Esmeralda county, for $60,000.

On Minerals.

[Notes of a Lecture delivered before the Mechanics' Institute by A. W. Jackson, Jr., Instructor of Mineralogy, Petrography and Economic Geology, at the University of California.]

(Continued from Last Week.)

Metals.

Of the known metals eight occur rarely and seven not uncommonly in the native state. The more commonly occurring metals are arsenic, bismuth, copper, silver, mercury, gold and platinum. Mineralogically, there is little to be said of them. Like the metallic salts, they are confined to the upper portions of ore veins, and for the *same reason*, viz: they result from the reduction of some other ore of the same metal, with the exception of *gold*, which seems to be deposited at once in the metallic state when first formed.

Gold and platinum also occur in what are familiarly called "placers," but in every such case they have been derived, of course, from some other deposit.

Thiometallites.

The last of the ore orders, is the extremely important one of metallic sulphides. The minerals of this family hold much the same relation to those of the first three ore families, that the sclerites hold to the zeolites, and hydrolites.

They are, namely, the primitive or original ore minerals from which most of the metallic salts, oxides, and native metals are derived by secondary decomposition, that are confined mostly within a comparatively narrow zone, close to the surface of the earth.

For several metals the sulphide or "sulphuret" ores are of the first importance from the economic standpoint; thus: Lead glance for lead; copper pyrites for copper; smaltine for cobalt; nickelite for nickel; cinnabar for mercury; zinchlende for zinc. Chemically, the minerals of this order consist mainly of sulphur, arsenic or antimony, combined with one, two or more of the heavy metals. Sometimes the chemical composition is very simple, as in galena; at other times six or eight different elements occur in the same mineral, as is often the case with the fahl ores. If we turn now to the physical properties, we shall find that the greater number occur with a brilliant metallic lustre and color, yellows and grays being predominant. The conditions of their formation are such that we frequently meet with most exquisite crystal forms, which, of course, are different for every different species, and which assist greatly in determination. On the other hand, they also occur in enormous bodies of massive or compact material quite free from crystals. These masses are made up either of one single mineral, like iron pyrites or copper pyrites, or, as is more frequently the case, of an intimate mixture of several. Thus, the bodies of ore known as the "bonanzas," on the Comstock lode consisted mostly of galena, silver glance and stephanite.

I have already indicated the geological occurrence of these ores as being below the oxides and native metals on ore veins in general below the "water line," and from here downward they persist to indefinite depths.

They are also found less commonly in ore beds, interstratified in the crystalline schists and sedimentary rocks, and rarely disseminated in the massive crystalline rocks.

This order is conveniently subdivided into three families, named after the most commonly-occurring mineral in each family: Pyrites or pyritis, galenitee or glaucee, cinnabsrites or blendes.

I will mention in a few words the distinguishing characteristics of each family and give the leading minerals of each.

In the first family are comprised all of the sulphides, arsenides and antimonides of the hard, magnetic metals—iron, nickel and cobalt. Some copper and silver minerals are included, but in every case iron enters largely into the composition, while in the other two families the soft, non-magnetic metals appear. The luster of all is brilliant metallic; color, yellow, white, red, and all are very hard and brittle. One can strike fire with pyrite.

The most common members are pyrite, the commonest iron compound in the order, and, until quite recently, the most worthless. Iron is now made from it in England to the extent of £50,000,000 annually. Mispickel, the white metallic sulfarsenide of iron, is sometimes met with in our California gold veins, and is always dreaded.

The red and white nickel ores, from which most of the nickel of commerce is obtained, and smaltine, the leading ore of cobalt, belong here; likewise, two important copper ores, peacock copper ore and copper pyrites, both of which occur in this State in sufficient quantities to form some day the basis of a thriving copper-producing industry.

Glances.

The glances likewise possess metallic lustre, but the colors are the dark grays and blacks instead of the light yellows, and whites of the preceding family. Copper, lead and silver are the principal metals combined with sulphur, arsenic and antimony.

Copper glance is an important ore of copper, while another copper mineral, viz.: Fahl ore is highly valued for the silver which it almost invariably contains. It is the principal silver ore in the Blind Springs district, Mono Co., Cal.

The richest silver ores belong here, viz.: Argentite or silver glance, silver copper glance, and brittle silver ore. These are the silver minerals that one invariably reaches, sooner or later, on silver veins (to which may be added, perhaps, the ruby silver ore of the next family). While there is a large number of lead minerals in this family (18) only one is of value, viz.: Pb S and that of the greatest value for Pb.

Come West, Young Man.

The Arizona *Democrat* says: If nature has endowed you with some energy, a fair amount of "grit," a modicum of common sense, a willing hand and a not too sluggish head, come West! If you are willing to earn your bread in accordance with the fore-ordained destiny of man, come West! If you are willing to take your chances in the fierce and eager race for wealth and distinction among the young, active and enterprising element of the frontier, come West! If you are prepared to fight the battle of life, and have the nerve and staying qualities that can snatch victory from the jaws of defeat, come West! If you are the happy possessor of a light heart that can smile at fate and take the whips and scorns of outrageous fortune serenely, come West! If you have a good constitution, an honest heart and a not too elastic conscience, come West and grow up with the country. You may, perhaps, think that we are asking for too many good qualities and natural gifts in a young man from the East. We are aware that it is difficult to find many who will fill the bill, but we are also aware that these are the qualities that command success in a new country. They are qualities to some extent native and to the Western manner born. They are the rule and not the exception among the young, active, go-ahead spirits of the border, and he who is deficient in them had better not enter the lists for fame or fortune in the far West.

We claim that to-day there is not a finer field on the globe, for the display of every attribute that goes to make a man, than the Western States and Territories. The doctrine of the survival of the fittest here finds its truest exposition; merit and true manhood here finds recognition and appreciation. The youth who was born with a silver spoon in his mouth is treated with no more consideration than his plebian neighbor who had to be content with an iron one. Men are placed upon their natural level, with a fair start in the race of life, and the goal is first reached by him whose pluck, and bottom, and staying qualities are the best. So, young man, if you think that nature has equipped you with the gifts that will enable you to hold your own in the rough-and-tumble fight for fortune on the distant frontier, by all means, come on. We will give you a hearty welcome, a fair start and a good send off. You will find a country worthy of your best efforts, and a people not slow to acknowledge them. You will find a land with grand resources, blessed with a perfect climate, and endowed by the Creator with every natural advantage to make a great and prosperous State. So, come, be one of us, take your share in our grand heritage, cast your lot with our future, and take part in the glorious fruition of our hopes, so near at hand. Turn your steps to a region, the sun of whose future greatness, just rising above the horizon, is shedding its golden beams over valley, mountain and mesa, and whose midday splendor will cover with a blaze of glory this favored land. Come to Arizona, the mineral monarch of the Western world, which will yet become—

"The State of every State the pride,
Beloved of Heaven and all the world beside."

The Alta has put in a new blower to furnish more air for the lower levels, which have been very hot, and is better prepared than ever to work the mine.

A Triumph of Engineering.

The Work on the Hoosac Tunnel.

The Hoosac tunnel, with all the delays, mistakes and disappointments connected with it, is a grand achievement. It is one of the great works of our time. Already 20 passenger and as many freight trains pass through the tunnel daily. Every morning through this gateway of the Green mountains roll the cars whose wheels, the evening but one before, began their revolutions at St. Louis, beside the Father of Waters. More than 300 cars daily carry their burden through this new avenue of transit. Following to a great extent the line of the natural water-courses on the route, the easy grades thus secured cheapen the cost of transportation from California and Dakota, from the cornfields of Illinois and the wheatfields of Minnesota to Massachusetts bay, and a cent less of freight on each bushel of grain or barrel of flour means millions of dollars saved to the consumers of bread in New and in Old England.

Enormity of the Work.

If for nothing else the tunnel would be worthy of notice as a triumph of engineering. Some may think that it was only a question of Patrick with his drill and plenty of gunpowder and time; and that to go through a mountain is no more than to go through a hill, or a short rock cutting, except that the process is lengthened with the distance. But "time is money." It would take 50 years to go through the Hoosac mountain, beginning at any point on one side, and burrowing to the other. We could not wait for that. No one, not even a State Government, would put capital into a work the end of which was to be reached only after half a century. So the tunnel must be begun at more than one point. Here, at once, is involved a nice problem of engineering. Working simultaneously from opposite sides of the mountain, it is no longer Patrick burrowing through by whatever zigzag course he may chance to take, but these tunnelings from opposite sides must be so directed that they shall finally meet, and fall into an accurate line of adjustment. How shall this be done? As any one can see, who gives the matter a moment's thought, a slight deviation from the mathematical line required would cause the two arms of the tunnel to miss each other. The width of the tunnel is 24 ft. It is only necessary, therefore, for the approaching excavations to swerve from their true place at the point of expected junction by anything more than half that measure, or 12 ft., in order to slip by each other, and go farther asunder, instead of coming together. Who will measure and set the angle which shall determine the momentous difference in such a case between success and failure? The tunnel is to be nearly five miles long. Each channel from the opposite sides of the mountain will therefore be nearly two miles and a half in length.

Delicate Calculation Needed.

The problem, then, is to run two lines of excavation through a mountain, with no visible point in front to aim at, as the engineer has in the open field, and yet to have them so nearly coincident in direction for a distance of 12,000 ft. each that they will not miss each other, but form one continuous whole. No Creedmoor rifle needs to be aimed so nicely in order to hit the bull's-eye. No allowances for wind to swerve or the power of gravitation to draw down the ball from its proper course render the marksman's problem so difficult of solution as the engineer's in this case. An error in the sighting of his instrument amounting literally to a hair's breadth would send the arms of his excavation wide asunder into the bowels of the dark rock, leaving his tunnel no tunnel at all, but only a worm's track in the mountain. But the problem in this instance was still further complicated. To hasten the completion of the tunnel by providing additional faces on which the workmen could operate, as well as for the purpose of ventilation, it was determined, as we have seen, to sink a shaft from the top of the mountain to the level of the tunnel, midway between the two ends. Two factors were thus at once added to the problem: First, to fix so accurately the point on the mountain at which to begin the downward excavation that when, after working by faith for four years, the estimated time necessary, the miners should have reached the requisite depth, they would be in the exact line of the projected and partly completed tunnel; and, secondly, from that pit in the depths of the mountain, to be able to aim their course in either direction so correctly as to be sure of meeting the company of miners approaching them from both extremes of the tunnel. In short, here were four tunnels to be made at the base of the mountain at one and the same time, another from the summit perpendicular to them, and all to be exactly in the same plane, on penalty of the failure of the entire enterprise! It was a difficult problem. But it was solved most triumphantly. When the headings from the central shaft and from the eastern portal came together, as come together they did, their alignments swerved from each other by the almost infinitesimal space of five-sixteenths of an inch.—*The Atlantic.*

THE Virginia and Gold Hill Water company says it is ready to lay another pipe from the Sierras to Virginia if any more hydraulic pumps are wanted. To lay the pipe would cost well on to $500,000, yet they are willing to take the chances on the lode.

Useful Information.

HOW TO BUILD A STORAGE WAREHOUSE.—A storage warehouse, to be absolutely safe, should, in the first place, be entirely detached. It should be built around a court, and the windows, protected by iron shutters, should all face inward, and be as few and as far between as is consistent with needful light. The building should be in many sections, being subdivided by strong brick walls, the necessary connections being by double iron doors—that is, by doors with a space of at least a foot between them. The court-yard of the building should be provided with several hydrants, and, in a shed adjoining, a fire engine, with an engineer always on duty, should be placed, the still further protection of electric communication with the fire department being provided. Each floor of the building should be furnished with a hydrant with hose attached, and the floors should be so arranged as to be slow burning, if not made of fire material. The roof also should be fire-proof in character. Were these features of construction embodied in a building of the general character above indicated, the community would be justified in feeling that goods stored within it were as nearly safe from such disasters as overtook the Morrell warehouse in this city recently as is possible in the present state of the arts. With the constant and increasing demand for storage, we think, as a business enterprise, the erection of a building entirely safe would prove a profitable investment.

REMOVING MILLSTONE GLAZE.—The Fry process for taking off the glaze of millstones, which was so much talked of a few years ago, was as follows: First the burrs must be put in perfect face, well dressed, out of wind, and in the best possible condition for grinding. They are then run a couple of hours until they become warm, taken up, and washed with aqua ammonia in the following manner: Take four ounces of aqua ammonia (spirits of hartshorn) and thoroughly saturate the stones with a good sponge, and let them stand over night. By doing this once a week, or oftener if necessary, the glaze will be kept off. His second method was to take two ounces each of borax, washing soda and muriate of ammonia, and dissolve them in a quart of warm water; then add cider vinegar. Now cover the stone with sand, and apply the solution with a sponge. Leave it on 10 minutes, and then dry the stones thoroughly. This is said to harden the burrs so that nothing, not even garlic, can glaze them, and they will retain their natural temper and grit for weeks, and will not glaze.—H. W. MILLER.

HOW TO DISCOVER SEWER GAS.—I purchased several ounces of essence of peppermint. Late in the evening I went to the fourth story, turned on the water from the hot-water faucet for several minutes, and then, allowing the flow of hot water to continue, poured the essence into the outlet from the basin. Returning to my library, I inquired from my wife if she noticed any peculiar smell in the house. She said, "No." I requested her to go to the kitchen and ask the same question. She did so, and immediately one of the servants exclaimed: "Why, I was just telling Ellen that there was a smell of peppermint candy in the kitchen." The next day, with my plumber, repeating the experiment, and tearing up the cellar bottom, we found a crack in the soil pipe. I understand the Health Department of this city has within a year to two adopted this mode for detection of sewer gas.—*N. Y. Post.*

TO PREVENT SPERM OIL FROM GUMMING.—If kerosene oil is added to sperm oil it will prevent the latter from gumming. Mix thoroughly 100 parts of oil with 4 parts chloride of lime and 12 parts of water. Now add a small quantity of the decoction of oak bark to destroy all traces of gelatinous matter still remaining, and allow the impurities to settle. Next agitate the clear part with a little sulphuric acid; settle once more and remove the acid by washing, and see to it that none of the acid remains. If the oil shows any signs of becoming rancid, it ought to be boiled with water and a little bicarbonate of magnesia for about 15 minutes, when it will likely lose the power to redden litmus paper.

THREAD FROM WOOD.—The manufacture of thread from wood for crochet and sewing purposes has, it is said, recently been commenced in the middle of Sweden. It is wound in balls by machinery, either by hand or steam, which, with the labeling, takes 1 minute and 12 seconds, and the balls are packed up in cardboard boxes, generally 10 in a box. Plenty of orders from all parts of Sweden have come in, but as the works are not in proper order, there has hardly been time to complete them all. The production gives fair promise of success, and it is expected to be very important for home consumption.

CORN (MAIZE) GRINDING.—There is probably no better method of reducing (grinding) corn than with a pair of ordinary millstones. The dress usually adopted in the West where a 4-foot stone is used has 12 leading furrows with 4-inch draft; 12 second furrows, laid off from a circle 12 inches in diameter, and 12 short furrows laid off from a circle 24 inches in diameter. The furrows are deep at the back, feathering out to the front, and leaving a light catch at the edge of the land. The lands are cut at an angle of 45 degrees with the draft and about 1-16 of an inch apart.

A NEW CEMENT FOR JOINING LEATHER and other materials is now being introduced into England by the proprietors of the Morris Patent Engineering Works, Birmingham. The article is called dermatine, and is made from a peculiar preparation of the intestines of animals by a special process worked in Austria, the material being imported into England for the finishing process. Owing to the elasticity of the dermatine, the joints are as pliable as the other parts of the belt, while it is stated that the tensile strength of the cemented joints has been shown by tests to be equal to that of the entire leather. Dermatine is melted and applied the same way as glue, and a considerable saving is effected as against joints made by means of mechanical fastenings.

WATER-PROOF COATING FOR BRICK.—Two solutions are necessary, the first composed of one pound of castile soap in a gallon of boiling water; the second, of two ounces of alum to a gallon of water. Apply the soap solution first, let it dry 24 hours, then apply the second, thus alternating until three or four coats each have been applied. The soap solution should be applied at a boiling head; the alum solution at 60° to 70° F.

CLEANING WHEAT.—Shears, a student of modern milling, concludes that wheat should not be handled too tenderly in cleaning. "In twelve years experience," he says, "I have never seen wheat overcleaned. No smutter using steel or chilled iron surfaces has ever scoured wheat too much, if unbroken. The brush is a great help, but it is not intended to take the place of the smutter."

DEMAND FOR LOCOMOTIVES.—The Baldwin Works have given the Pennsylvania Railroad Company an answer as to the time in which the order for 60 locomotives placed with them by the latter company can be completed. The time fixed is the 1st of July, and the Pennsylvania Railroad Company will build 210 locomotives at its own shops during the year.

WEIGHT OF AIR.—A cubic foot of air weighs 538.1 grains, or something over 1 ounce; 13.06 cubic ft. weigh one pound. About 65 cubic ft. of air furnish 1 pound of oxygen. An apartment 8 ft. high, 12 ft. wide and 13 ft. long contains about 100 pounds of air: and a room 40 ft. square and 18 ft. high contains about a ton.

PAINT FOR BRICK WALLS.—A cheap paint is made for brick walls by simply mixing up good hydraulic cement in water. The natural tint is neutral and pleasing, but may be readily varied. This paint cannot be washed off by storms, nor peeled off by the sun.

IT is said that there are upward of 3,000 steam-plowing machines now employed in England and Scotland.

Good Health.

A Commercial View of Life and Death.

The London *Sanitary Record* quotes a recent writer on vital statistics who calculates that of 10 children born in Norway, a little over 7 reach their twentieth year; that in England and the United States of America somewhat less than 7 reach that stage; that in France only 5 reach it, and in Ireland less than 5. He tells us that in Norway, out of 10,000 born, rather more than one out of three reaches the age of seventy; in England, one out of four; in the United States, if both sexes be computed, less than one out of four; in France, less than one out of sight, and in Ireland less than one out of eleven, and he adds this significant computation, based on what may be called the commercial view of the vital question: In producing dead machinery, the cost of all that is broken in the making is charged to the cost of that which is completed. If we estimated by this same rule the cost of rearing children to manhood, if we calculate up the number of years lived by those who fell with the years of those who passed successfully to manhood, there would be found between the two extremes presented in Norway and Ireland—both, be it observed, unnatural—a loss of 120% greater in the first year of life, 75% greater in the first four years of life, and 120% greater in the years between the fifth and the twentieth, in Ireland than in Norway. In Norway the average length of life of the effective population is 39, and rather more than a half, years, in England 35½ years, in France not quite 33 years, and in Ireland not quite 29 years. Thus, again comparing the best with the worst of a scale of vitality, in which both are had, in Norway the proportion of the population that reaches 20 survives nearly 40 years, or four-fifths of the effective period, to contribute to the wealth of the community; while in Ireland the same proportion survives less than 29, or considerably under three-fifths of the effective period.

PERFUMES AND OZONE.—It is discovered that perfumes exert a healthy influence on the atmosphere, converting the oxygen into ozone. Cherry, laurel, clove, lavender, mint, juniper, fennel and bergamot develop the largest quantity of ozone. Flowers without perfume do not develop it, but the flowers of narcissus, mignonette, heliotrope and lily of the valley develop it in close vessels. Odorous flowers, cultivated in marshy places, would be valuable in purifying the air.

Hints about Eating Breakfast.

Having tested a number of meals in a general way, eating more or less each time, find out as near as may be what is the proper amount for a meal. Begin with a very light breakfast of ordinary food, such as you have been accustomed to, and note the number of hours you can go without feeling a want of more food. For a very light breakfast, say one roll, a cup of coffee and a very small piece of meat, three hours or less will be found the limit. This is not offered as a rule, but as a suggestion, for it makes a vast difference what you do in those three hours. A given amount of food will go farther in manual labor, as brain work is more exhausting than hand work. The next time try a little more, and in the course of a dozen breakfasts you will learn to judge pretty closely what you require to carry on your work till the hour of the next meal. Having found out just what you need, never on any consideration, take more. Never mind how nice the steak, how tempting any food may be, shut right down on the whole eating business the instant you have had enough. Too little can be repaired by eating a light lunch before the next meal. Too much cannot be repaired, and you must pay for the indiscretion. In all this there must be plain common sense. Do not imitate the invalid who kept a pair of scales on the breakfast table to weigh his daily bread. Eat and be satisfied, and then stop.—*Food and Health.*

SAND BAG FOR THE SICK-ROOM.—One of the most convenient articles to be used in a sick-room is a sand bag. Get some clean, fine sand, dry it thoroughly in a kettle on the stove; make a bag about eight inches square of flannel, fill it with the dry sand, sew the opening carefully together, and cover the bag with cotton or linen cloth. This will prevent the sand from sifting out, and will also enable you to heat the bag quickly by placing it in the oven, or even on top of the stove. After once using this you will never again attempt to warm the feet or hands of a sick person with a bottle of hot water or a brick. The sand holds the heat for a long time, and the bag can be tucked up to the back without hurting the invalid. It is a good plan to make two or three of the bags and have them ready for use.

VARIATIONS IN STATURE.—A contributor to the *German Militia Wochenblatt*, who has lately been employed in mustering and examining the recruits drafted into the German army, has established by a long series of careful measurements, not only that the hight of a man varies very considerably at different times of the day, but also that this variation takes place with great regularity in every individual man. The greatest difference in hight observed was an inch and a half.

SICK-ROOM.—Food should not be left in a sick-room, but after the patient has tasted of it remove it, if no more is wanted, immediately. Never keep it by the sick one with the hope that he or she may partake of it by-and-by.

THE EYES.—Avoid glaring and glancing lights in the rooms where you read, sit or write. Mirrors which strongly reflect the light in a room are very bad for the eyesight, and produce evil results at last. A very bright carpet, even, is bad for weak eyes. Use cold water freely in the morning after sleep.

RUBY-DUNDERBERG.—We notice that at the recent Ruby & Dunderberg Con. M. Co.'s meeting in London a very earnest disposition was manifested to place Mr. Rickard, late manager of the Richmond Con., in charge. The stockholders wanted a practical man at the head of affairs who understood mining in Eureka district. One gentleman said that if Mr. Rickard was going to be connected with the Ruby-Dunderberg, he would himself subscribe for one-half the proposed new issue of shares. This was an old shareholder in the Richmond Con. The following resolution was carried: "That the capital of the company be increased to £325,300, by the creation of 25,300 new shares of £1 each, to be called new shares, each new share to entitle the holder thereof to a dividend equal in amount with the dividend on each of the original £10-shares in the company, and the new shares, in all other respects, to give the same rights and privileges as the original shares." It was also resolved that the new shares were to be offered in the first instance to the holders of the original shares, in the proportion of one share for each original share held, and any new shares not taken up may be allotted by the Directors to such persons, and on such terms, as they may see fit. The new shares are to be paid for at such times and by such instalments as the Directors may determine. Mr. Rickard was present at the meeting, and in answer to a question said that, if he had charge of the mine, he would do the best he could to make returns to the stockholders.

THE mineral discoveries on the upper Pecos, N. M., are attracting considerable attention.

AN old Spanish mine has been discovered in the Ladron district, northwest of Socorro, N. M.

THE flow of water from the mouth of the Sutro tunnel is 6,824,631 gallons in 24 hours.

Leather Belting, H. Royer, S. F.
Pipe Joint, Francis Smith & Co., S. F.
The Pacific Business College, San Francisco.

Passing Events.

The beautiful weather of the latter part of the week is a fitting conclusion to the rainy prelude, for the warmth following the moisture will set everything growing luxuriantly, and before we know it, spring is upon us. While we hear of heavy snow storms in the mountains, we know that, unpleasant as they are to experience, the result will be a good supply of water for miners' use the coming season.

This week we issue a double edition of the MINING AND SCIENTIFIC PRESS, and give special prominence to the prospectore, or class of men to which the Pacific coast owes more than to any other, being as they are the pioneers in all the new regions, and opening the way for capital to follow and develop the resources.

As we go to press the good news comes that the Chinese Bill has passed the House by a vote 177 to 65. The debris question still remains undecided here. Almost any day now Judge Temple's decision may be expected, and it is awaited with anxiety.

MINERS and prospectors are not doing much in the Black hills, northeast of Prescott. Mr. Jacoby and the Minges brothers went there recently and found snow six ft. deep on top of the range.

Production of the Precious Metals.

An Abstract of the Census Monograph on the Bullion Output of the Country.

First Paper.

The Government printing office at Washington will shortly issue a monograph upon the production of precious metals in the United States. Although published first, it will form the concluding chapter of a forthcoming volume devoted to the technological aspect of the precious metal industry. That volume will contain an elaborate discussion of the distribution of precious-metal mines and their methods of exploitation, together with abundant data on the mechanical, chemical and metallurgical processes employed in the industry, all classified and treated from a statistical point of view.

The general direction of this branch of the census inquiry was committed by the Superintendent of Census to Hon. Clarence King, then Director of the United States Geological Survey.

For purposes of convenient administration, he divided the United States into three leading divisions:

The division of the Pacific, consisting of the States of California, Nevada and Oregon, and the Territories of Arizona, Idaho, Utah and Washington; an area made up of the States and Territories bordering on the Pacific ocean and the political divisions of the Great Basin. The leading reason for this arbitrary grouping of political divisions is that they are for the most part tributary to the great mining center of San Francisco. A very large portion of the capital employed and of the personal ownership center in San Francisco, which is also the source whence the greater part of the mining machinery, appliances and materials are drawn.

Personnel of the Pacific Division.

The headquarters of this division was placed in San Francisco, and the direction of the work confided to Mr. Geo. F. Becker, U. S. Geological Survey, geologist in charge of the Pacific division.

Mr. J. M. Cunningham, for the eastern portions of Washington and Oregon, and the northeastern part of California.

Mr. J. S. Curtis, Nevada, south of the line of the Central Pacific railway.

Mr. J. H. Hammond, central and eastern counties of California.

Mr. D. B. Huntley, Utah, southwestern Nevada and portions of California.

Mr. H. W. Leavens, the tract lying west of the Cascade and Coast ranges in Washington, Oregon and northern California.

Mr. Walter Nordhoff, southeastern and middle Arizona.

Mr. H. W. Sander, Western Arizona.

Mr. Luther Wagoner, southern California.

Mr. Albert Williams, Jr., Idaho, Nevada north of the Central Pacific railway, and the Comstock lode.

Personnel of the Division of the Rocky Mountains.

The division of the Rocky mountains adjoins the division of the Pacific on the east, and extends eastward as far as the 100th meridian, including the State of Colorado and the Territories of Dakota, Montana, New Mexico and Wyoming. At the head of this division was placed Mr. S. F. Emmons, U. S. Geological Survey, geologist in charge, with headquarters at Denver.

Mr. W. B. Fisher, portions of Lake, Chaffee, Clear Creek and Gilpin counties, in Colorado, and Beaverhead county, in Montana.

Mr. Wm. Foster, Montana and Wyoming.

Mr. J. E. Hardman, the smelting works in Lake county, Park and Summit counties, and portions of Clear Creek and Gilpin counties, in Colorado.

Mr. Charles Cotter, New Mexico.

Mr. E. H. Schaeffle, Dakota and portions of Colorado.

Mr. W. G. Sharp, San Juan, Hinsdale, Gunnison, La Plata, Huerfano, Ouray and Rio Grande counties in Colorado, and portions of New Mexico.

In addition to the census experts, the following-named gentlemen acted as temporary assistants: Messrs. Herman Garlichs, J. C. Hine, H. B. Price, H. L. Simmons and W. H. Whittlesey, in Colorado, and W. F. Wheeler, in Montana.

Personnel of the Eastern Division.

The eastern division comprises the whole territory lying east of the 100th meridian. Prof. Raphael Pumpelly, U. S. Geological Survey, was placed in charge, with headquartere at Newport, R. I.

Mr. Geo. H. Eldridge, Southern States and reduction works east of the 100th meridian.

Prof. N. S. Shaler, with the assistance of Messrs. Joseph M. Wilson and J. E. Wolff, New England States.

To each of these three chiefs of division was committed the responsibility of choosing his own assistants, who were in due form appointed by the Superintendent of Census as special experts.

All the leading precious-metal districts of the United States were visited by the corps of experts, and their observations were entered in the field upon a uniform system of printed schedules.

The following list shows the number and character of reports returned, which form the basis of the statistical tables in this publication:

Deep mines	1,967
Placer mines	325
Amalgamating mills, concentration works, chlorination and leaching establishments	327
Smelting works	86
Arastras	25
Total number of reports	2,730

The entire work of compilation and tabulation has been performed under the personal direction of Mr. Albert Williams, Jr., special expert in charge of compilation. Mr. Williams was formerly connected with the MINING AND SCIENTIFIC PRESS, and was well qualified for the task, as the result shows.

Method Followed in Compilation.

Three principal methods have been adopted by statisticians in studying the bullion production of the United States.

The first and most obvious plan has been to use as a basis the receipts of domestic bullion reported by the several Mints and U. S. Assay Offices, ascertaining the probable total product by adding to the figures thus obtained the amount shipped abroad, as shown by the Custom House returns, and the probable amount consumed in the arts. The objections to this method are, the amount coined within a certain period does not necessarily correspond to the production for that period. In the same way the proportion of the domestic product exported may be largely affected by the stock of precious metals on hand at any given time. Both of these variations depend primarily upon fluctuations in the bullion market and international balance of trade. An average of a long series of years would give tolerably accurate results, but for any stated period the figures of coinage, export and consumption in the arts are apt to be deceptive.

Assuming the source of the bullion deposited at the mints to be correctly stated, there are still serious and unavoidable defects in the custom-house statistics, notwithstanding the care taken to secure accuracy. No account is taken of bullion transported overland into Canada, nor are the export figures for dore bullion, base bullion, ores and matte shipped abroad always to be depended upon. This difficulty is particularly manifested in the last three instances. The regulations prescribed by the custom-house authorities are not followed by penalties sufficient to insure accurate invoicing of the values thus exported. It is well known that during the period of intense speculation in gold a very large proportion of both receipts and exports even of gold coin was entirely hidden from official scrutiny, with a still greater margin in the bullion movement; and although the inducements to a concealment of the actual movement do not now exist in the same force, it is still doubtful whether the official figures are entirely reliable. A less important source of error is the undisputed fact that not infrequently bullion of domestic production, after having been shipped abroad, is, from changes in the silver-bullion market or from the necessities of coinage, reimported into the United States.

It will thus be seen that the best results which can be hoped for from the most careful application of the "consumption and export" method are close approximations extending over considerable periods, but not the exact product for any given year. The system also fails to segregate the yield according to the productive source; and while the geographical distribution by State and Territorial lines may be shown, it is hardly possible to carry the analysis further and ascertain in this way the yield of single districts or even counties.

The Director of the Mint has examined the bullion product of the country critically from the "consumption and export" point of view, employing as a supplementary means of information the details obtainable by correspondence and circulars scattered through the mining districts. The substantial accuracy of the estimates of the total production thus reached has been fully borne out by the results of the present investigation.

The second, or "transportation," method consists in estimating the product from the statistics of the express companies, freight lines, and banks which have the handling of the product from its original sources. This plan would give more satisfactory results if, in the first place, all the bullion, ores, etc., were transported from the producing points through these different channels alone; and if, in the second place, none of the product were reshipped from point to point, and thus twice recorded. As a matter of fact, there is a considerable portion of the gold yield sent through the mail as registered matter, and a large proportion passes from the productive source into the market through private channels. Both of these means of conveyance are affected by proximity to main lines of communication; or, on the other hand, by the absence of express or railroad facilities; and in neither can the exact effect of these circumstances be very definitely counted upon. In the Pacific States and Territories, the great bulk of the mine output is handled by Wells, Fargo & Co.'s express, and upon the detailed returns of the many offices of this company, Mr. J. J. Valentine, General Sup't, has been enabled to furnish very valuable estimates of the bullion production, covering a long series of years. The business connections of this express company in portions of the country not covered by their agencies have rendered it possible for Mr. Valentine to frame approximate estimates of the product of the mining territory outside of that from which Wells, Fargo & Co. are the principal transporters of bullion.

(TO BE CONTINUED.)

Forms of Locations for Prospectors.

We append a few forms for taking up claims under the United States mining law, each one of which explains itself. They will be found useful to prospectors, as they can make out their notices before leaving camp, filling in the blanks when on the ground:

Notice of Location.

Notice is hereby given that the undersigned, having complied with the requirements of Chapter Six of Title Thirty-two of the Revised Statutes of the United States, and the local customs, laws and regulations, has located —— linear feet on the —— lode [twenty acres of placer mining ground], situated in —— Mining District, —— County, ——, and described as follows:

[*Describe the claim accurately (by courses and distances, if possible,) with reference to some natural object or permanent monument, and mark the boundaries by suitable monuments; if a placer claim is located on surveyed land, describe the legal subdivision.*]

—— ——, Locator.

Discovered ——, 188-.

Located ——, 188-. Recorded ——, 188-.

Attest: —— ——.

NOTE.—Record of location notices, in absence of a District Recorder, should be made with the proper recorder of deeds for the county wherein the claim is situated. It is advisable to have these notices attested by witnesses, for locatore cannot be too careful about their evidence.

In re-locations to increase width of surface ground under the local law, or to more particularly identify or describe the claim, use the above form, but state after the description that it is a re-location, and in addition, where the original location is recorded, in order that the title may revert back to the original discovery.

In locations of abandoned mines, the fact that it is such a location should be stated, and the affidavits of two or more respectable parties that such mine was abandoned and subject to re-location should be recorded with the location notice.

Where the location is by agent, that fact should be stated after the name of the locator, thus: By Thomas Jones, agent (or attorney).

Proof of Labor.

—— of ——, County of ——, ss.

Before me the subscriber personally appeared ——, who being duly sworn says that at least —— dollars' worth of labor or improvements were performed or made upon [here describe claim], situated in —— mining district, —— county, —— of ——, during the year ending ——, 188-. Such expenditure was made by or at the expense of —— ——, owners of said claim, for the purpose of holding said claim.

[Jurat.] —— —— (Signature).

NOTE.—The record of an affidavit like the above is *prima facie* evidence of the performance of such labor.

Notice of Right to Water.

The undersigned claims the water running in the —— stream to the extent of —— inches for mining purposes, to be conveyed by (ditch or flume) from this point to the —— placer claim.

—— ——,

Dated ——, 18—. Locator.

NOTE.—This notice is to be posted near the outlet, and the following form is to be duly recorded in the district or county recorder's office.

Pre-emption of Right of Way for Ditch and Location of Water.

To whom these presents may concern—know ye, that I, ——, of the county of ——, in the State of ——, a citizen of the United States, do hereby declare and publish as a legal notice to all the world, that I claim and have a valid right to the occupation, possession and enjoyment of all and singular, that tract or parcel of land lying and being in the county of ——, in the State of ——, for the exclusive right of way for the purpose of constructing a flume or water ditch from —— stream to —— placer claim, more particularly described as follows: Commencing [Here describe the exact route for ditch or flume.]

I also claim and have a valid right to the enjoyment and use of —— inches of water from said stream for mining purposes, to be conveyed through such flume or water ditch to said claim, together with all and singular, the hereditaments and appurtenances thereunto belonging, or in anywise appertaining.

Witness my hand and seal this —— day of ——, A. D. 18—.

—— ——

[*Name*]

Notice posted on the stream ——, A. D. 18—.

Ditch commenced at claim or at stream ——, 188-.

—— of ——, county of ——, ss.

On this —— day of ——, 188-, before me, a —— in and for the county aforesaid, in the State aforesaid, personally appeared ——, to me personally known to be the person who executed the foregoing written instrument, and acknowledged that he executed the same for the uses and purposes therein set forth.

Witness my hand and official seal.

—— ——.

OVER 10,000 people are working directly and indirectly in Montana Territory on the line of the Northern Pacific.

MONTANA people expect an addition of 30,000 to their population this season.

Foundry Notes.

Centrifugal Pumps.

Perhaps no class of machinery has undergone a greater change and improvement during ten years past than centrifugal pumps. Only ten years ago they were regarded as a wasteful kind of water-raising engine that had nothing to recommend them except the absence of valves and cheapness of first cost, but now we find them competing in economy with the best appliances of other kinds in Holland and elsewhere, where low lifting is done.

The economy of centrifugal pumping has been mainly due to English engineers.

There are now three firms whose main business is the construction of such pumps, and as before remarked, the "coefficient of effect" has been steadily raised, until investment, and all things considered, it is doubtful if any other system can compete for lifts of 30 feet or less.

The pumps of commerce, that is, those made for sale, irrespective of the duty to be performed, are, of course, imperfect machines, and cannot be expected to attain economic results. The pumps must be arranged to suit the hight of the lift, and otherwise to meet the requirements of particular cases.

By examining the circulars relating to centrifugal pumps and the rated capacity, the area of suction, discharge, and so on, it will be seen that in many cases it will take from 30 to 40 pounds pressure per square inch to propel the water through the pipes. This is all wrong. The rating of pumps by the English firms referred to is about one-half what is claimed by the makers in this country, or to state the same another way, the orifices and ducts for inlet and outlet are twice as large. The exponent of capacity for a centrifugal pump is the area of the suction pipes. Water flows into a vacuum at the rate of 40 ft. a second in a straight pipe; 30 ft. is working limit, so that anyone may compute the true capacity of a centrifugal pump from this factor. The economy of working is, however, another matter. This depends upon a number of conditions, to notice which would exceed the extent of our present remarks.

On April 9th of last year, the PRESS noticed the centrifugal pumps made by the San Francisco Tool company, of this city. Since that time the company has executed a contract with the city of Sacramento for machinery to lift the sewage and surface-water at that city, and has proved the value of its methods of construction such pumps. From computations by Mr. L. F. Bassett, City Engineer at Sacramento, the duty performed was equal to more than 10,000,000 gallons per diem with a pump of the following dimensions: Area of foot-valves, 200 inches; area of suction pipe, 175 inches; area of discharge, 150 inches; area of out-put pipe, 300 inches; speed of pump (maximum), 275 revolutions a minute.

From such data as a common working test afforded, the effect produced is estimated at 65%.

The whole plant, including an extra expensive steam boiler, has cost (exclusive of buildings) less than $6,000, and this we regard as the most remarkable feature in the case.

The pump was of the vertical or straight line type, from designs by Mr. Richards, the Superintendent. The rotor, as explained in our previous article, is wholly unlike any constructed by other makers, being nearly the same as a turbine water-wheel inverted—that is, the curves reversed and made theoretically to the form that meets the conditions of action—paraholic curves. Another feature of these pumps before noticed is a water space between the runner and casing. This is, so far as we know, a new departure from all practice, including the English firms, who have gained such high results with plain paddle-runners. There is, no doubt, much power lost by friction, and there is also no doubt but this friction is lessened by a stratum of water of some depth, instead of a mere clearance.

The company has recently supplied a pump of about 6,000,000 gallons capacity, to be used on Rough and Ready island, in the San Joaquin valley. The working effect, we cannot speak of at this time, but we have no doubt it will meet the expectation of all concerned.

We headed our former article, "A New Home Industry," and we once more call attention to the value of such machinery for reclamation and irrigation, with the further remark that this industry here bids fair to excel both Eastern and European attempts in the important matter of economy.

It may be as well to supplement the preceding remarks by some extracts from the Sacramento *Record-Union's* interviews with Mr. Bassett, the City Engineer. A very fair test of the value of the arrangement was made when the entire sewage of the city for eight days, including a rainfall of more than two inches, was discharged from the city in what would be less than 24 hours' running of the pump to its full capacity. The sewage and drainage is all discharged into a lake, during the time the waters of the river are high, and from this lake the pump forces it into the river.

During the short time that the pump was run in this way, the sewer pipes in the lower part of the city, which had become almost entirely filled with a deposit of mud from having an insufficient outlet, were nearly cleansed of the deposit and very much relieved. The general arrangement by which the above results have been attained is substantially as follows: From the end of the sewer-pipe at Sixth and V streets, a ditch has been cut through an old slough to Eighth and Y, connecting with the lake. The lake has been connected with the pumping works, where a pit or sump has been put in, over which the pump has been set. This pump is run by what would generally be rated at about a 50-horse power engine (from 50 to 100), however, will not make any practical difference in the amount discharged by the pump, the resistance under such circumstances being only about one seventy-fifth part greater. By having the pump arranged in this way we avoid raising the water several feet higher than is necessary during low water, to let it fall back again; that is, we avoid requiring the water to "march up hill, and then march down again," as a certain French army did in olden time. The pump is so built that it is very durable, and can be placed in constant service for a number of years, needing only slight repairs, those parts that are most subject to wear being easily and cheaply replaced. Quite large substances can pass through the pump without injuring it; in fact, almost anything that would be brought to it in the sewage. In this connection it may be interesting to note that at the time the pump was first started up a large quantity of catfish were pumped out of the lake and discharged into the ditch on the outside of the levee, several hundred of them being caught by the boys and Chinamen who happened along at that time. Most of them were as large as those usually sold at the markets.

"OFF ON A PROSPECT."

SNOW SLIDE.—A dispatch from Bodie, dated the 20th, says: John I. Ginn, J. C. Kemp and John F. Keating came in from Lundy on snow shoes Sunday evening, and reported a terrible accident in Lake canyon as a result of the recent storm. On Wednesday night a snow slide occurred which buried several men, four of whom were killed. Their names are Robt. Trumbull, Alex. McKeon, D. B. Grant and Henry Schumaker, the three former miners and the latter a machinist and engineer, recently arrived from San Francisco, where he leaves a wife and three children. The bodies of all but Grant were recovered on Friday and left on the snow. During the night another snow slide occurred, and they were buried under 45 ft., where they now are. In all, upwards of 40 ft. of snow slides occurred in Lake and Mill Creek canyons between Wednesday and Saturday, and in all 38 people were buried in the canyon; and at Tioga district, where the great Sierra mining company is operating. The only serious injury done to any persons, except those heretofore stated, was to Christian Hahletzel, who was under eight ft. of snow 19 hours. He was alive Sunday morning, but little hope was entertained of his recovery. The snowfall in Mill Creek canyon averages six ft., and higher up in the Sierras eight to ten ft., and in the immediate neighborhood of Bodie about 4 ft.

THE AUBURN TRAMWAY.—District Attorney McMillan, who has had considerable experience in running tramways, went to the Auburn C. G. M. Co.'s mine, at Dun glen, last week, to assist in getting the new tramway in order. He returned late Saturday night, and reports everything in splendid order. The tramway is 3,029 ft. long, and extends from the mill into the mine. The ore cars are filled from a chute in the tunnel, and clutched to an endless wire cable, run by machinery at the mill, to the battery floor, where the ore is dumped. Considerable delay has been caused by the weather, which has been unusually severe, but every obstacle has been surmounted, and the mill will probably start to-morrow.—*Silver State.*

MINERS everywhere are at work with full supply of water, and good work is being done in every section of Trinity county.

A Prospecting Trip.

The engraving on this page depicts a scene familiar to most miners who have ever done any extensive prospecting. It represents a miner and his "pard" just starting off on a prospect, with a full outfit of tools, arms and provisions, and ready for anything. It is turn about to tow the old pack mule, and to ride. The drawing from which this engraving was made was done by the late Charles Nahl, a noted artist, who was, as a miner himself, familiar with such scenes, and its faithfulness any old prospector will attest.

Prospectors do not all have an animal to ride and a pack mule, too, by any means. Some of them only have a hurro to pack, and others "tote" their own grub. Most of them nowadays, where camps are plenty, go from day to day from their cabins, never staying away over night. But in newer regions, where distances are magnificent and the mineral range wide, a well-equipped prospector must take all his conveniences with him.

There used to be a legend in Arizona that, when a prospecting expedition was about to start out, and the mule was being packed, the crows and buzzards would come and light on the trees and fence near by, surveying the preparations with complacency and commenting mentally on the physical condition of man and mule; it was only a question of time when the whole outfit would come to the crows and buzzards. If the climate did not kill them, the Indians would—so it amounted to the same thing. Still the prospectors kept going, and though many of them fed the crows, those who did not, found claim after claim, until finally the knowledge of the mineral wealth of the region was forced on to the people of the United States, and Arizona became what it is. It is to the prospector that the prosperity of this and other regions is due, since, without their labor, attention would never have been drawn to the natural resources of the country.

Probably there is no greater feeling of independence and freedom than that experienced by men in starting out on a trip of this kind. An absolute freedom of movement and thought, a sensation as of care left behind, a certainty that no telegram will reach you, or other outside business distract your attention; a buoyancy born of hopeful feelings and anticipation of good fortune; necessities provided in advance for a specified time at least; a confidence in your own resources, and that certainty of success which every prospector has, combine to make such moments long remembered with pleasure, as the writer remembers them in days gone by.

SUCTION FANS.—The suction fans now in use on the Comstock—one at the Bonner shaft, one at the old Consolidated Virginia and a third at the Sierra Nevada shaft—are proving very valuable aids in ventilating the lower levels. They have now been in use a sufficient length of time to allow of their value being very justly estimated. With one of these fans in operation a shaft will carry off as much foul air from the underground regions as would two shafts of the same size without the suction apparatus. Such fans are likely to come into use in other places along the lode and at mines in other camps in the State. The cost of running is small.

UPON the request of Katata, the condemned Indian murderer, Judge Deady has shortened the time of his execution at Portland, Oregon, to Tuesday, the 28th inst., instead of Friday, the 31st. The prisoner made this strange request so that his friends, who must leave by the steamer of the 29th, could witness his execution and carry back to his people his dying words.

SMELTING WORKS.—Wm. Gay was in town this morning and informed our reporter that he had about completed arrangements for erecting smelting works on a copper location at Spenceville. The parties mostly interested in the enterprise are residents of Nevada City. There will probably be a big copper boom at Spenceville as soon as the weather becomes settled.—*Grass Valley Tidings.*

THE CONSUMERS' COMPANY.

VULCAN B B,

The Best Low Grade Explosive in the Market.

SUPERIOR TO BLACK OR JUDSON POWDER.

VULCAN NOS. 1, 2 AND 3,

THE BEST NITRO-GLYCERINE POWDERS MANUFACTURED.

Having secured large lots of the best imported Glycerine at low prices, we are prepared to offer the mining public the very Strongest, Most Uniform and Best Nitro-Glycerine Powder at the very Lowest Rates.

SPECIAL INDUCEMENTS IN PRICES.

VULCAN B B POWDER (in Kegs or Cases) IS UNEQUALED FOR

BANK BLASTING AND RAILROAD WORK.

Caps and Fuse of all Grades at Bottom Rates.

The Central and Southern Pacific Railroads Use Vulcan Powder and No Other.

S. HEYDENFELT, President.
H. SHAINWALD, Secretary.

VULCAN POWDER CO.,
218 California St., San Francisco.

Carson and Colorado Railroad.
(NARROW-GAUGE.)

The Company announcee the completion of its line March 1. 1882, to CANDELARIA, Columbus Mining District, Esmeralda Co., Nev., 188 miles from Mound House (Junction with Virginia and Truckee Railroad).

STAGE CONNECTIONS,

At Hawthorne with U. S. Stage Company's daily coaches for Aurora (26 m.); Bodie (37 m.); Lundy and Bridgeport.

At Luning (125 miles from Mound House) with Gilmer, Salisbury & Co.'s tri-weekly stages (leaving Tuesday, Thursday and Saturday mornings) for Grantsville, Belmont and Tybo.

At Belleville (150 miles from Mound House) with Belleville and Independence Stage Co.'s stages for Benton (49 m.), Bishop Creek, Big Pine and Independence.

At Candelaria, with U. S. Stage Co.'s stages for Columbus (8 m.), Silver Peak, Montezuma, Alida Valley, Gold Mountain, etc.

THROUGH TICKETS

To the above points for sale at San Francisco, Sacramento Reno, Carson and Virginia R. R. Ticket offices.

This is the direct and natural route for Passengers and Freight, to points in Southern Nevada, Mono and Inyo counties, California. The line, laid with steel rails and redwood ties and equipped with new and first-class rolling stock, is penetrating new and most promising Mining Districts which are now attracting deserved attention throughout the country.

For information on through freight rates apply to

H. M. YERINGTON, Gen'l Supt. D. A. BENDER, Gen'l Freight & Pass. Agent. Carson, Nev.

COMPOUND OXYGEN

NEW TREATMENT BY INHALATION for Consumption, Asthma, Dyspepsia, Catarrh, Bronchitis, Rheumatism, Headache, Debility, Chronic Neuralgia, and all Chronic and Nervous Disorders. Prepared by DRS. STARKEY & PALEN, Philadelphia, Pa. Package contains all directions, and is easily sent by express, ready for use AT HOME. H. E. MATHEWS, San Francisco, Agent, 606 Montgomery street, San Francisco, Cal. Send for Free Pamphlets.

BOONE & MILLER,
Attorneys & Counsellors-at-Law,

Rooms 7, 8 and 9
No. 320 California Street, S. F.,
(Over Wells Fargo & Co.'s Bank)

Special Attention Paid to Patent Law.

N. B.—Mr. J. L. Boone, of the above firm, has been connected with the patent business for over 15 years, and devotes himself almost exclusively to patent litigation and kindred branches.

J. H. WYTHE, M. D.

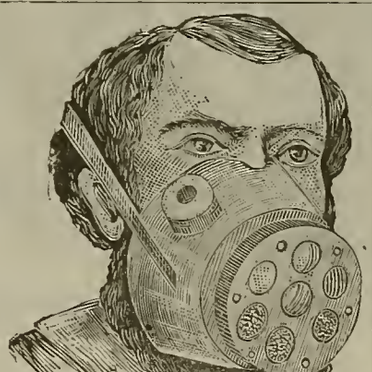
PATENT

LIFE-SAVING RESPIRATOR

Prevents Lead Poisoning and Salivation.



INVALUABLE to those engaged in Dry Crushing Quartz Mills, Quicksilver Mines, Guano Works, White Lead Corroding, Feeding Threshing Machines and all occupations where the surrounding atmosphere is filled with dust, obnoxious smells or poisonous vapors. The Respirators are sold subject to approval after trial, and if not satisfactory the price will be refunded. Price, $3 each, or $30 per dozen. Sent post-paid to any address upon receipt of price.

Address all communications and orders to

MINING PROPERTIES EXAMINED AND REPORTED ON
FRISCO, BEAVER COUNTY, UTAH.

1851. 1881.

DEPUTY U. S. MINERAL SURVEYOR.

Surveys for Location or Patent. Maps and Plans Drawn. Mining Properties of all kinds examined and careful reports made of the same. Consultations on Mining Investments. Address, THOS. W. REECE, CIVIL ENGINEER, Oroville, Butte Co., Cal. References given and required.

EDWARD BOOTH,

Chemist and Assayer,

No. 110 Sutter St., S. F.

This paper is printed with Ink furnished by Chas. Eneu Johnson & Co., 509 South 10th St., Philadelphia, and 59 Gold St., N. Y. Agent for Pacific Coast—Joseph H. Dorety, 527 Commercial St., S. F.

Scientific, Mining and Other Valuable Books.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS Office, S. F.

BY GUIDO KUSTEL.
MINING ENGINEER AND METALLURGIST.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequaled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery etc., which alone are of the greatest value. PRICE, $7.50

ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver. 1880.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 155 pages, embracing illustrations of furnaces, suplements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.

Price, $3.00 coin, postage free.

PRINTERS, AUTHORS, INVENTORS, PATENTEES, BUILDERS, MANUFACTURERS, MACHINISTS, MERCHANTS, and other trades-people can have satisfactory Engravings and Electrotypes made at moderate prices by the S. F. ENGRAVING CO., No. 405 KEARNY ST. Send photographs, sketches, drawings, models or samples for estimates. Map and Woodcut Engravings enlarged or reduced by the aid of photography, at less than one-half the cost of the originals and in short time. Photo-relief, Zincograph and other improved methods employed.

Rare Cabinet of Minerals.

A physician who has long resided in the mines and other parts of California, and gathered a large and valuable collection of minerals and other specimens, offers the same for sale at a bargain. Address "Cabinet," box 2301, San Francisco.

Outfit for Prospectors.

To obtain a suitable outfit is the first duty of the prospector, and the following list of articles and suggestions may be of some value to those uninitiated in this sphere of life:

He should have two pairs of thick blankets, a buffalo-skin or, if possible, the more luxurious comfort afforded by a pneumatic rubber mattress and pillow, which are very light, pack closely (after the exhalation of air), and, by protecting the body from the emanations that arise out of the damp ground, prevents disease by increased accommodation; two strongly buckled leather straps, for securing blankets, mattresses, etc., when packed for traveling; a suit of strong gray clothes, a change of flannel underclothing, a slouch cap and a strong pair of boots; a Henry or Spencer breech-loading rifle; a full-sized Tranter's, Smith & Wesson's, or Colt's six-shooter; a leather holster with waist-belt, and a good hunter's knife; a mule or a mustang horse, accustomed to mountain life; a bridle having a short whip attached; a horned saddle fitted with rings for securing blankets, saddlebags, water canteens, etc.; one of the stirrups (I prefer the left) should be fitted with a tube for receiving and supporting the muzzle of the rifle, the upper end being suspended by a leather yoke, so riveted at its middle that one loop can be tightened on the taper rifle stock, and the other passed loosely over the saddle-horn, that it may be freed for immediate use when necessary. This same yoke can be used for "hobbling" the animal at nights, by punching two holes at a suitable distance from the ends, to allow sufficient freedom to the legs, when securely tied with buck-strings, through these holes, and then stop-knotted, so that the animal shall not stray too far away, when the scattered pasturage prohibits the use of a picket-rope. A small "poll" pick and a light and solid wrought-iron baking-dish of the shape of the prospector's pan, to be used, as required, for either purpose. An eight-inch wrought-iron frying-pan, a coffee-pot, tin cup, fork and spoon, a good supply of matches, some soap, a towel, etc; a blow-pipe, with suitable tools and fluxes for testing and assaying.

These, with a pocket compass and spy-glass, constitute a first-class prospector's outfit, and with such (excepting only the buffalo-robe, mattress and pillow), the writer has made a lone journey of 800 miles, over 14 ranges of mountains, in 30 days, cooking bread and victuals, en route, from the following provisions: Flour, 14 lbs.; bacon, 11 lbs.; tea, ½ lb.; a box of yeast powder, with pepper and salt. These, varied and assisted by two jack-rabbits shot on the way, deserted with good digestion, were more relished than better food would have been under less active and invigorating circumstances.

It would be folly to attempt a minute description of the general subtleties of sage-bush cookery, as most men will succeed therein as well as I did, and will be enabled to get on sufficiently well to prevent starvation (if not to realize the value of tasting grief, that they may learn to live more contentedly afterwards), and necessity will dictate many varying dishes, by roasting, frying and stewing.

There is, however, one suggestion that may enhance comfort, when passing through an unusually dangerous Indian country, when fires must be avoided at or near your camping-ground, and cold collations become a consequent necessity. In such circumstances, I boiled, when in security, one-fourth of a pound of tea in a quart of water, for 10 minutes, and after removing the leaves, continued the boiling of this strong tea-water until it evaporated to about a pint, which I carried for use when required; it will be found that one spoonful of this, when added to a cup of water, makes a much more palatable and refreshing beverage for washing down your frugal meal than water, and it will prevent the headache that will otherwise result. A good remedy for the headache, in still more dangerous journeys, is to chew either of the agreeable and nourishing herbs, tea or coffee, as many do the useless and disgusting weed, tobacco.

This, being under peculiar circumstances, was worse fare than such men generally enjoy, and as I was alone, and traveling over strange ground, my poor, unfortunate animal, even thus freighted, with self, supplies, etc., had to pack 250 lbs. 30 miles per day, under a scorching sun, over mountains and alkaline flats, partaking of her scanty fare of chance bunch grass, during the night, most miserably restricted by hobbles. Mules have been much extolled for this work, and they may be better on the hard mountain; but, for the general purposes of exploration, the good, hardy, enduring mustang, if free from vice, is not only faster, but much easier for the rider, and on soft ground travels freely, where the mule, sinking deeper, from insufficient area of foot, is retarded at every step; moreover, the mule's back is too ridiculously strait for the requisite stability of the saddle when traveling over undulating country, and this alone would favor the use of the horse. As to their comparative measures of amiability, neither can claim much superiority, for the old saying of "Stubborn as a mule," may be equaled by a new one, "Wicked as a mustang."

These desirable equipments are often curtailed by a deficiency of cash, and those that are imperatively necessary are selected at discretion; but, in no instance, (unless prospecting for a lunatic asylum), should he expunge more from the list than the horse or mule, with their appendages, the buffalo-hide, rubber mattress, pillow, one blanket, and the rifle; then he should, if possible, obtain the substitute of a faithful donkey, to pack his baggage and share his solitude.

Before moving yourselves away from water and grass, it will be necessary to resort to your most superior judgement for the whereabouts of the next suitable camping-ground, which I have seldom failed to anticipate from the following considerations:

In viewing a distant mountain, take particular care to measure with the eye the extent of mountain slope that is drained by any particular canyon; for, the greater the expanse of such surface of drainage, the more likely you are to find water. Granite, by absorbing less, yields more surface water than clay slate, and clay slate more than limestone. Snow-capped mountains are more to be relied on, in such positions, than those that are uncovered. Patches of willows, cottonwood, wild oats, rye, and other greens, indicate, by their extended growth beyond the mouths of canyons, the pressence of water, which may often be seen at great distances.

Water frequently runs, during the night and early morn, much farther down the flats than after the sun's meridian heat has evaporated a portion of the running stream and its upper tributaries; so that, in apparently dry rivulet bottoms, moisture if not water, may be found a few inches under the surface, showing that it has recently run thus far, and the probability that it still flows a little higher or near to the mountain gorge.

Where water runs, grass will also be almost invariably present, in sufficient quantities for transient feed. If darkness should overtake you before reaching such a canyon, your animal will find water, by superior instinctive faculties, if unrestricted by reins, much sooner than you can.

It may be occasionally necessary to ascend a mountain that is deeply covered in snow, to examine some prominent out-crop; and if you have not the regular 10 ft. long by 4 inches wide snow-clog, you can readily make a substitute, by interlacing a few willows to form a support of two ft. long by one ft. wide, with holes in a suitable midway position for securing them under the shoes or boots. These will bear you up in very soft snow, and are much more easily made, carried and used, than the others, which require considerable practice, for much advantage.

In making the last-named snow-shoe, it is better to round off the outside corners and finish to the shape of a half-moon.

In cold-weather traveling, it will also be very necessary to resort to extra artificial means for keeping the hands and feet warm, and a pair of kid or buckskin gloves or mittens, lined or covered with flannel, will be ample for the hands; while a bar ey sack, cut into rectangular halves, wrapped and tied around the boots, will be superlatively effective in preventing the feet from becoming cold and frost-bitten. If you have no cord for securing the half-sack, you may first cut the sewing of the barley sack, and then, after cutting it straight through its longest diameter to form two triangles, they may be bound around the boots, then secured under the hollow of the sole, and over the instep, by knotting the acute-angled ends of the canvas.

Being thus prepared, the important questions arise: Where to prospect? Which formations should be sought? And what should be avoided.—*Phillips' Explorers', Miners' and Metallurgists' Companion.*

Undercurrents.

A large proportion of the gold, as it exists in deposits of gravel, is disseminated through it in small particles, or what is ordinarily denominated as flour gold, and without the introduction of proper mechanical appliances to save these particles in the process of hydraulic mining, a large amount is necessarily carried away by the action of the swift currents of water through the sluices. The knowledge of this fact has led to the adoption of what are known as undercurrents, and it has been found that by their use the product of gold in nearly all of the mines worked by hydraulic force has been very largely increased.

Undercurrents are formed by building large, flat boxes, or platforms, by the side of and a little below the main sluice boxes. Their size and shape depend, to some extent, on the facilities afforded by the contour of the ground where they are to be constructed. Triangles, irregular oblongs, and parallelograms, containing a superficial mean surface of from 500 to 1,000 square ft., are the forms generally adopted. They are designed to receive from the main sluice boxes a certain portion of the finer gravel wash, black sands, quicksilver and amalgam, and to afford to the particles of gold and amalgam a better chance to settle permanently in the riffles, which are evenly disposed over the whole surface of the platform. For this purpose an opening is cut across the bottom of the main sluice boxes from 15 to 18 inches in width. In this opening are inserted steel bars 1 inch square and 1 inch apart, generally fixed in a cast-iron frame and forming a grating. The small particles of gravel, sand, gold, amalgam, etc., which pass through this grating, are caught in a box placed below the sluice boxes, set on a pitch of about 1 inch per foot, whence they are carried by the force of the water, which also falls through the grating on to the platform (or undercurrent), which is provided with check boards and riffles. This platform is laid on a grade of from 10 to 12 inches per each 12 ft. of length, and has an opening at its lower end so arranged as to return the bulk of the material received upon it to the line of the main sluice boxes below. In order to distribute the water and material received from the main sluice boxes evenly over this platform, a series of check boards are placed at its upper part, in a direct line with the box, under the grating of the main sluice, which first receives the discharged material. As the water, gravel, etc., flows out of this box, part of it strikes against the nearest check board and is turned down the platform, the remainder, flowing in, is diminished and distributed by each succeeding check board, and an even flow over the whole platform is thus obtained. At the lower end of the platform the discharge of the water, gravel, etc., into the main sluice boxes below may be arrested by the insertion of a small box, on a grade, into which the material drops from the riffles.

The undercurrents and main sluice boxes discharge their contents into a deep and strongly-framed box laid with a heavy stone pavement. From the upper part of this box a continuation of the main sluice leads the gravel stream to other undercurrents, drops, etc., and thence to a final point of discharge. The lower part of this box must be 4 or 5 ft. deeper than the point from which the main sluices are continued, and will be found to be of great service in catching fine gold, amalgam, etc.

The gratings in the main sluice boxes necessarily deprive the latter of a considerable quantity of water. To counteract this loss, the main sluice boxes are narrowed about 6 inches to contract the current of water, until both streams, that of the undercurrent and that of the main sluice boxes, reunite as before described.

Undercurrents will be found to be of important service in catching rusty gold, which cannot be touched by quicksilver, and which, lessened in specific gravity by the finer matter enveloping it, is very liable to be carried entirely through a long line of sluice boxes to the final discharge, and consequently lost. The gentler flow and shallower space, and larger distribution over the platform of the undercurrent, gives to this rusty, as well as to the fine or flour gold, greater chances to be caught by the more extensive riffle surface.

Riffles are generally made of wood; sometimes of wood covered with strap iron; but in all cases where there is a limited or very little fall, a great advantage will be gained in using riffles made only of iron, as the smooth surface reduces the resistance to a minimum, while the spaces for catching the valuable metals can be largely increased.

For undercurrents the following form of construction is suggested: Let the iron bars be 1¼ inches wide, 1 inch thick and from 12 to 14 ft. long, fitted into cast-iron cross supports, which serve to hold them in place and allow spaces of three-fourths of an inch between each. These cross supports are slotted so as to hold the longitudinal bars firmly, and are made about 2½ ft. long. This form of riffles will be found advantageous in cleaning up, as they can be easily handled, and their wear can be made even by turning them over, and end for end alternately, in each succeeding run. The cost of riffles for an undercurrent 10 ft. wide and 48 ft. long will be less than $500 in San Francisco, and it is believed that, by their use in the form suggested, a large saving of gold can be effected.

How to Work Flat Claims.

Some time since a description appeared in the Oroville (Butte Co.) *Mercury*, describing the claims of the Oroville Mining and Irrigating Co. Mr. O. P. Powers, one of the principal owners and manager, put into the claim an arrangement for raising gravel, which was described in the journal referred to. We quote this description here, as the method of working the claim adopted may be useful in other localities where the ground is of similar character:

A few hundred yards below where Mr. Powers has worked for several years past, is a flat piece of ground that in summer is but little above the level of the river, and in winter, when the river is high, is entirely covered with water. The bluff near by is soon to worked, which will cover the flat above referred to with tailings and other debris. But how to work the flat was the question. There was no fall, and of course no place to dump the tailings. He has been for the last month working in this way: He has made a flume and laid it on top of the ground, commencing at the river and running back, say 400 ft. The last piece of the flume is 48 ft. long, and connected with the next box in such a way as will admit of its being raised or lowered, and stands at an angle of about 45°. A head of water of 100 inches, with 200 ft. pressure was being used. The nozzle of the pipe entered the head of the flume about one ft. The head of the box was otherwise closed tightly and covered on top about one ft. The balance was open, the same as any other flume-box. Where this piece of the incline flume connected with the next box was covered on the top to prevent water, gravel and stones from going over; they would thump up against the top, fall down and be carried off.

This is the whole process: Shovel the earth into this open flume, set up at an angle of 45°; turn on the water and it will go up the flume like a shot out of a gun, bump up against the top after going through the first joint of the flume, fall into the second box to be carried off the same as in any other flume. While watching the four men employed shoveling the earth into the flume, Mr. Powers tumbled a 60 or 70-lb. rock in, which was carried up the incline with ease into the flume beyond. They have been at work only one month, and burrowed a large hole in the earth, into which Mr. Powers has placed a chief and turned on the water, loosening the gravel by the car-load, which flows into this slanting flume and is driven up into the level box. As they are near the river and below its surface, from 75 to 100 inches seepage water is constantly coming into the works, but does no damage; it soon runs into the slanting box, and it, too, is driven up the 48 feet of incline into the almost level flume beyond.

We desire to state here that this slanting flume-box, 48 ft. long, is lined on the bottom and sides, inside, with wooden blocks, the same as those usually found at the bottom of flumes, so that the space inside of this flume was one foot wide by something over two feet in depth. It is a simple contrivance for mining level ground, where a head of water for driving purposes can be obtained. Any man who ever made a flume-box can make one, and that, too, at a cost of less than $100, including the blocks to line it. It is one of the simplest things on earth, and ought to have been found out years ago. It has been in operation over a month, and been examined by mine owners in this and adjoining counties, who pronounce it a complete success. No part of it wears out faster than the ordinary flume, except at the upper end, where the rock and gravel bump against the covering, which wears out very fast. Should timber be used for covering instead of boards, it would last a longer time.

Small Batteries.

Probably there is no one thing more needed by the mining community than a cheap quartz crushing appliance. That is, one that costs little to build, little to transport and little to run. Dozens and dozens of things have been tried over and over again; but we have always had to come back to the old-fashioned stamps again, which, notwithstanding all efforts to displace them, still maintain their supremacy. A stamp battery, however, does not by any means fulfill all requirements; for, while it does its work well, it is originally expensive, and weighs so much as to cost considerable to transport. It is not expensive, when the work it accomplishes is considered; but having to pay out so much money at once for it in the beginning is objectionable.

In some places in this State gold is crushed out of rock by a hand mortar; in other places, by spring pole and mortar; in other places, by arastras. In some localities mills with light stamps are used, when the character of ore admits of it. Up in Granite Basin, Plumas county, in this State, in addition to the large mills with 850-pound stamps, there are two smaller ones with light stamps. One of these has 9 stamps, 5 of which weigh 300 pounds each, and 4 of 200 pounds each. One mill has 4 stamps of 400 pounds each.

Mr. D. Van Lennep, of the locality mentioned, gives to the Director of the Mint his experience with these small batteries, which will interest many of our readers. He says:

Having had an opportunity to try the capacity and effectiveness of the small batteries used in this place, I will more particularly bring them to your notice. Of the two batteries used to crush the rock of the mine, one consists of 4 stamps, weighing each 200 pounds, the other of 5 stamps, weighing each 300 pounds. The stamps are given a fall of about 4½ inches, and made to fall 110 to 120 times in one minute. The cams are single instead of double, as in the common California battery. The rock of the mine is about three-fourths of medium hard quartz (that is, neither very brittle nor tough), and one-fourth small pieces of quartz and earthy material. Trials under my eyes have showed that the 200-pound stamps crush about one ton to the stamp in 24 hours, and the larger of 300 pounds stamps crushes about one and a half tons to the stamp in 24 hours. This result is exceedingly satisfactory, considering the easy transportation of the light machinery and the easy handling—two great advantages in mountainous regions. The light batteries do not need the skilled labor of millwrights to be put up. The estimate of cost is reduced to more than half of a heavy battery. The gold is extracted in the same way as in large batteries—that is to say, that the free gold is amalgamated in the battery with quicksilver, and by running the pulp on copper plates having a coat of quicksilver or silver amalgam. Rude contrivances, to concentrate sulphurets and catch hard amalgam run off the plate, consist of coarse sacks laid across the tailings sluice. These sacks are taken out every day or every 12 hours and washed in tanks. The ledges are mostly in the hands of the discoverers or of persons of small means, and are worked in a small way, giving handsome returns if handled with knowledge. The ledges are small, from 6 inches to 3 and 4 ft. wide. Free gold is about from $3 to $12 a ton in the rock. The sulphurets are rich, but no attempt has yet been made to work them. The bedrock is a soft granite, and cost of extraction small; wood is in great abundance.

H. M. Newhall, a California pioneer who died last week in San Francisco, left $2,500,000. The deceased possessed real estate in this city, San Mateo, Santa Clara, Monterey, San Luis Obispo, Los Angeles and Ventura counties. He also held stock in various corporations and railroad and municipal bonds.

The California Iron and Steel Company.

The California Iron and Steel Company, whose furnace and worke at Hotaling, Placer county, we illustrated last week, was incorporated for the purpose of utilizing the iron deposits of thie coast, and to keep the money at home now annually sent to foreign countries to purchase pig iron, har iron, plate iron, cut nails, and steel ingots. All of these branches it is the intention of thie company to eetablish upon this coast. The Directore are: Egbert Judson (President), George W. Gibbe (Vice-President), B. B. Redding, A. P. Hotaling and Irving M. Scott. To show the scope of operations proposed hy the company (the office of which is in San Francisco), and its present status as well, we publish its prospectus in full, as follows:

As a sure supply of the raw materials ie the basie of a permanent and enccessful business of this natnre, the company have purchased from the California Iron Company their extensive heds of iron ore, together with its furnace, charcoal kilns, wood lende, roads, ditches, etc., in accordance with the following schedule:

Land (timber), 7,800 acres, @ $5	$39,000.00
Roads (coal and iron), 31 miles	7,147.15
Buildings at furnace	8,783.67
Kilns (20 patent kilns, capacity 45 cords each)	30,869.63
Blast furnace	82,536.46
Bridges across Bear river, etc	2,700.00
Ditches and reservoirs	7,120.26
Rights of way for roads, ditches and railroad	3,755.00
Dwellings, offices, stores, stables, etc	7,531.86
Attorney's fees	3,500.00
Opening limestone ledge	950.00
Engines, blowing cylinders, boilers and fixtures	26,570.00
Hoisting engine, reels, boiler feed-pump	2,000.00
Vertical engine, with shafting, pulleys and fixture	2,137.00
Rock-breakers, shafting, elevators, etc	2,800.00
Ore on dump and at furnace, 4,700 tons @ $2.40	11,280.00
Pig iron (1,640 tons @ $20)	32,800 00
Cordwood (11,850 cords @ $2.50)	29,625.00
Coal (81,000 bushels @ 7c)	5,670.00
Horses, harness, buggy, carts, wagon	2,000.00
Mining tools and other tools (as schedule)	1,637.00
Blacksmith shop and fixtures	370.00
Book accounts	19,225.56
Cash in bank	4,176 87
Interest on $300,000 1½ years @ 6%	27,000.00
MINES.	
To purchase and development of Furnace mine, shaft No. 1; Limestone mine, shaft No. 2; Brown mine, shaft No. 3; Gray Iron mine, shaft No. 4; Paint Hill mines, shafts Nos. 5, 6 and 7, and Scott mines	53,430.00
Making a grand total of	$414,615.45

For a property improved and fully demonstrated. These bede of ore have heen long known to exist, and Senator Highy took a large qnantity of these ores East, in 1862 and 1863, and had pig iron, wronght iron and eteel made from it, all of which were of a high grade. State Senator Highy, of Calaveras, and Representative Neff, of Placer, introduced a hill for a State bounty, to he given to the first production of pig iron in California, 1864. The ores are principally limonite, rsd hematite and magnetic. The followiug analyses were mede hy Prof. Henry G. Hanks, State Mineralogist, and are taken from his report of 1880:

Limonite.—Clipper Gap, Placer county, contains 53.88% of iron.

Limonite.—Clipper Gap, Placer connty, contaius 56.58% of iron.

Ocherous Limonite.—Clipper Gap, Placer county, contains 55.93% of iron.

Magnetite.—Section 15, township 13 north, range 8 east M. D. M., Placer county, California.

ANALYSIS.

This ore contains 60.29% of iron.	
Silicia	3.23
Sesquioxide of iron	80.05
Protoxide of iron	17.06
	100.34

White Marble—Used as a Flux.—Section 15, township 13 north, range 8 east M. D. M., Placer county, California.

ANALYSIS.

Silicia	.15
Sesquioxide of iron	.35
Lime	55.72
Carbonic acid	43 78
	100.00

In making 4,429 tons of iron, the ore averaged 63% of iron.

During Novemher, 1881, in eeven samples from the bottom of all the deposits, the resulte from quantitive analysis were as follows:

No. 1 of Iron	62 1
" 2 "	63.5
" 3 "	63.1
" 4 "	65 2
" 5 "	60.3
" 6 "	62.6
" 7 "	64.17

These were from average eamples, and ehow that after yielding over 7,000 tone, the vein at 90 ft. deep contains the eame per cent. as at the surface.

Nothing practical wae done in the making of iron until the organization of the California Iron Co., in 1880, when active operations were commenced and puehed to a succeesful completion. The stack was put in blast April 17th, and firet iron made April 24th, 1881. The furnace produced 4,429 tons of firet-class iron of fine gradee—No. 1 heing soft and tough, No. 2 close and etrong—hoth excellent foundry gradee, mixing well with the hrande usually found in this market, and eepecially Oswego iron from Oregon. Noe. 3 and 4 are well adapted for and make good car wheele, chilling readily and evenly. It is now ueed for that purpoee by the Central Paoific Railroad Company, at Sacramento; Occidental Foundry, Arohitectual Iron Worke, and Golden State and Miner's Foundries of San Francisco, and hy David Leeter & Co., New Tacoma, Washington Territory, for Northern Pacific Reilroad. No. 5 is white iron, and used extensively for shoee and dies. Test pieces of casting, made from mixing Nos. 1, 2 and 3, gave, in a Fairbank's testing machine, respectively: 31,000, 31,000, 31,360 and 30,640 pounde to the square inch, tensile strain. While from soft pig of No. 1, hy the same machine, the results were, respectively: 17,857, 18,629, 18,387 and 18,300 ponnde per equare inch of tensile strain, the fractnre in each case showing a strong, fibrous qnality. These practical tests, and the use of several thousands of tone in the varions foundries, demonstrate the value and importance of this plant and miue. The quantity and quality of ore, flux and fuel have been fully demonstrated. The objects of the California Iron and Steel Company are:

First—To build a spur-track, 4' 8½" gauge, from the furnece to the Central Pacific Railroad, at or neer Clipper Gap. Distance, ahout four miles; cost, about $15,000. The iron will be furnished by the railroad company.

Second—Build a strap iron tramway, 30" gange, from furnace to kilns Nos. 1, 2 and 3, about eight miles; cost, about $6,000.

Third—To manufacture acetate of lime or pyrolignite of lime, turpentine, rosin, creposote, parreffine and wood spirits, or methylic alcohol, from the distilled vapors produced from the wood used in making charcoal, the sale of which products, in other places, not only pays the cost of making a better qnality of charcoal hy 25%, hut yields a profit of $3 per cord of wood used.

In the ahsence of factories producing these articles on this coast, a market is already provided for them; and should the California Iron and Steel company put into operation this plan, it will make a saving in the prodnction of Iron alone of $8 per ton, to say nothing of the *product* of the kilns.

Fourth—To purchase 25,000 acres of heavy timher for the manufacture of patent charcoal and the chemicals, as above described.

Fifth—To erect and maintain on a suitable location at or near San Francisco, a rolling mill, for the making of har iron and plate iron, to be constructed to roll nail plates for cut nail work, size and design of same to he hereafter determined hy the stockholders, the demand for which may be briefly etated to exist by the importation annually of hundreds of thousands of tons of har and sheet iron.

Sixth—To erect and maintain a cut nail mill to meet the requirements of this coast, where 246,400 kegs are annually imported, and not a single pound manufactured here.

Seventh—To erect and maintain a steel works for the manufacture of steel ingots and steel castings, to be nsed in the various hranches of industry.

Eighth—To erect and maintain smeltiog furnacee capahle of producing the raw materials, from which to manufacture the several articles above described, and to purchase iron ores, etc.

To carry out the above plan, the California Iron and Steel company have incorporated with a capital etock of $2,675,000, divided into 26,750 ehares, the par value of which is $100 each. Of these shares 15,990 are enhscribed for hy the former owners of the California Iron company, and 10,760 are offsred to the people of San Francisco, the stock to be delivered upon the payment of 25% of par value, which we hope will hs sufficient, without call for further assssments. The money obtained from the sale of which is to be applied to improvement of the facilities of furnace plant, and the purchase of a suitable site, and the erecting of the first section of the rolling mill. The other hranches will he added as fast as the stockholders and trustees shall determine.

Nickel and Cobalt.

[Written for the PRESS by C. H. AARON.]

How many of our miners, prospectors and assayers are on the lookont for these valuahle metals? Prof. Sterry Hunt says they frequently accompany cnpriferous pyrites and oxides of nickel, copper and cobalt have been found in considerahle quantities in Missonri. He also mentions their occurrence in a sample of ore from Western Nevada which carried 9% of copper. Hunt points out that the oxides of nickel and cohalt are converted into chlorides hy the action of a hot solution of copper chloride. Such an ore as that mentioned could be treated with such a qnantity of solution of hluestone and salt as wonld suffice to dissolve out the nickel and cohalt; the excess of copper in the solution removed hy digesting with a fresh lot of ore, or with several fresh lots, dieeolving nickel and cohalt from eech until all copper was removed by eubstitntion. In this way strong solutione might he got, free from copper, iron or lead. Antimony conld be easily removed, if preeent, and the oxidee or eulphidee of nickel obtained hy well-known methode. Each lot of ore, when freed from nickel and cohalt, could then he treated hy either of the two Hunt and Douglase processee for the copper; gold and eilver, if the ore contained any, heing aleo eaved. Prof. Blake reporte the finding of cohalt hloom in San Bernardino county. The writer hae aesayed a eample of *anabergite* from Esmeralda county, which contained 12 per cent. of nickel, and was informed that much better ore had been found there, though only in small quantities.

The fact that any euch oree have heen fonnd indicates a prohahility that valuahle minee may he discovered as the reward of intelligent eearch.

Our minere are not generally familiar with the ores of nickel and cobalt, and have directed their attantion too exclusively to gold, eilver and copper. In this matter, however, a certain progression is observahle. From 1849 to '59 the eearch was almost entirely confined to gold, in so far as the Western States and Territories were concerned. The discovery of the silver oree of the Comstock gave a new direction to prospecting, and from that time to the present silver has received at least an equal share of attention with the more valuahle metal. Quicksilver hae also heen actively sought and found. The present prominence of lead among the productions of the regions referred to, is due less to its intrinsic value than to its connection with the extraction of silver from the same or other ores. The production of copper in the United States, estimated at about sixty millions of pounde, has of late received important accessions from Arizona. A considerable quantity is obtained in California, and immense deposits of ore are said to await development in New Mexico. The euccess of iron smelting at Clipper Gap has set many hands and heads at work on schemee for similar enterprises at other points. Tin, though often sought and known to exist in considerahle quentity at Temescal, in the southern part of California, has not heen found, to any great extent at least, in other sections, nor profitably mined in that. Manganese is mined to a limited extent for home consumption. Chromium has of late years assumed a quite important plece among our products. Antimony has been successfully worked on a large scale, though operatione at Berkeley have heen euspended on eccount of the failure of a supply of ore from Arizona. Of nickel and cobalt we hear almost nothing.

Not only are miners unacquainted with the appearance of the ores of these metals, but a very large proportion of the very large crop of aseayers produced here within the last 15 years are equally uninformed on this point, and too many of them are not even competent to make nse of any method of detecting nickel or cohalt in an ore, not to spsak of making a quantitative assay, which indeed is not very easy to do correctly. Add to this that a considerable quantity of nickel or cohalt may exist in an ore, in conjunction with other and better known metals, without presenting any prominent characterietics to attract the attention; that they do not occur with great frequency; that many of the minerals containing them greatly resemhle, to the untrained eye at least, other less valuable snhstances; and finally, that assayers, as a rule, are not in the habit of doing any more work than they are paid for, and it ssems probable that not a few samples of nickeliferous and cobaltiferous ores may have heen found, and even assayed or worked for other metals, while these have escaped notice.

Although an accnrate assay of nickel and cobelt, hy the wet methods, ie not easy, nor in many oases possible, with the re-agents and apparatus at the command of the country assayer, yet a very good approximation may be obtained by a fire assay, either hy the hlowpipe or on a larger scale in the mufils, through the agency of arsenic, which often exists in the ores, or may he added if not naturally present. The mere testing for these metals is not difficnlt and every asseyer onght to be able at least to detect them if not to arrive at a reesonable approximation to their quantity. They frequently occur in conjunction with silver, copper, lead or hismuth, also with manganese.

Cohalt, fused in horax, on platinum wire, or on charcoal before the point of the hlue flame from the hlowpipe, gives a head which is small blue, whether hot or cold, and which cannot be decolored in the yellow flame, Nickel treated in the same way, bnt best on wire, gives a reddish-hrown head, lighter colored when cold than while hot, which hecomes first gray or black, and then colorlese if heated on charcoal in a yellow flame. These effects are sufficiently characteristic, bnt difficulties arise from the presence of other metals, which also afford colored heads with horax. Thus the presence of much iron on a little chromium may prevent the detection of cobalt in this way, and a large quantity of copper makes it difficnlt or impossible to determine nickel, while if all occur together, and other metals besides, the case is a bad one for any simple method. Of the two, cohalt is the more easily detected in mixed ores, and a method will he given hy which hoth may be readily found in en ore contsiuing all the more common metals.

A good test for nickel in a neutral or elightly acid eolution ie potassium or eodium zenthate or zanthogenate, which givee a yellow precipitate, eoluble in ammonia and reproduced by acetic acid. Thee reagents are extremrly eeneitive; with copper they give a precipitate which is aleo yellow, which cnrdlee hy ehaking, and ie distinguished from that of nickel hy being insoluble in ammonia. With a minute trace of cobalt, a dirty green precipitate ie prodnced, which is not dissolved hy ammonia. These reactione afford a ready meane of detecting nickel in presence of copper and cohalt in an ammoniacal solution, hy adding a drop or two of either of the zanthatee mentioned, filtering and adding acetic acid to the filtrate, when nickel, if present, will give the yellow precipitate.

The reagents are made hy adding bieulphide of carbon to an alcoholic eolution of caustic soda or potassa. Any excese of the hieulphide of carhon subsidee to the hottom, and the compound can be poured off and largely diluted with water for use; or, the whole may he allowed to dry hy evaporation, and the eolid reeidue dieeolved in a large quantity of water. Sometimes reddish, acicular crystale are formed, but the writer has not ascertained the conditions of their production, and it is not essential.

If to a solution of cobalt, in tartaric or citric acid, excess of ammonia be added, and then solution of red prussiate of potash, a dark red color is produced (Skey). A drop of cobalt solution added to a concentrated solntion of sodium sulphoizanide produces a hlue mass. Neither nickel, iron, manganese nor zinc interferes if the solution ie neutral (Schonn).

The solutions of nickel in acids are of a pale green color, which excess of ammonia changes to hlue. The similar solutions of cobalt are mostly pink, which ammonia cheugee to green, and, by exposure to air, to brown. The pink of cobalt ie complimentary to the green of nickel, and if the two metals are present in suitahle proportion, the solution is colorlese. Canstic potessa precipitates the hydrated oxides, which are soluble in ammonia, and in ammonium carhonate; also, to some extent, in sodium carbonate. Hydrogen sulphide does not precipitate these metals from solutione of the mineral acid salts, but doee from the acetates. These two facts afford the means of separating copper, silver, lead, hismuth, etc., on the one hand, and manganese on the other.

The ores of nickel vary greatly in appearance, being colored copper red, steel gray, white, brass yellow, dark green and apple green. Those of cobalt may be steel gray, tin white, crimson, peach-colored or lavender blue. Nickel is extensively used for making the alloy known as German silver, and for electroplating.

The chief use of cohalt is in the manufacture of pigments, and for coloring glass and pottery. It is therefore not reduced to the metallic state, but ie valued and sold as oxide.

Rock Temperatures.

At the last meeting of the California Academy of Sciences a communication was read from Chas. Forman, superintendent of the Forman shaft, on the Comstock lode, Virginia, Nevada, giving the temperaturee of the rock in the Forman shaft.

They are taken from the surface to the depth of 2,300 ft., as ascertained by drilling holes not lsss than 3 ft. deep into the rock, and inserting into the hole a Negretti & Zambra slow-acting thermometer, of the pattern adopted hy the Underground Temperature Committee of the British Association, and standardized at Kew. These holes were closed with clay, and the thermometers were left in for 12 hours, not less than three holes being tried at each point. The following are the depths in feet, and temperatures in degrees Fahrenheit:

Feet.	Deg.
100	50½
200	55
300	62
400	60
500	68
600	71½
700	74½
800	76½
900	78
1000	81½
1100	84
1200	89½
1300	91½
1400	96½
1500	101
1600	103
1700	104½
1800	105½
1900	109
2000	111
2100	119½
2200	116
2300	121

Old Timers.

The "old timer" is seemingly one of the fixtnres of the western mountains. No matter where you go he is there before you. He loves solitude, a dingy, smoky cahin, a white-eyed "cayuse," a yellow, mangy dog and a good gun. He has an unlimited supply of primitive ideas on the leading qnestions of the day, argument being his principal failing. We all know him, or, if we don't, can soon get acqnainted.

Although eccsntric in his habits and mode of living, he has a large heart—the "latch-string" of his cahin alwaye heing ont, his private pride consisting in befriending somo "poor devil" who is "ont of luck." When "old timers" meet, it's "hallo!" when they part, it's "eo-a-long!"

To the "old timer" whisky, bacon and coffee are the only staple articles—"terbaker" a necessity. He has a mortal hatred of the "tenderfoot;" women, in his mind, being a necessary evil, but, nevertheleee, an ahomination. I mnst remerk, in justice to the "old timer," that when he doee get "gone" on one of the fair eex there ie no "fooliehness" in his lovemaking—"pistole and coffee for two" often eettling little outhurete of jealouey, the "old timer" generally "getting away with the baggage."

He ie quite garrulone on the events of '49 and '50, and to dispute any of his assertione, although far etretched and improbable yarne, would cauee a light on the instant. The name of "injune" provokes him into ewearing in the choicest Eoglish, and when he is "red hot" on the subject, Spanieh oaths and invectivee mingle with the mother "lingo" with a eurprising fluency—hence the origin of the phrase, "he ewears hy note." Put a "biled ehirt," a "etandnp" collar and a euit of "etore clothee" on an "old timer," compelling him to wear them one day, and I'll warrant that he will cut his throat before night, if he isn't watched.

Any one failing to recognize the "old timer" of whom I epeak in this sketch had hetter take the advice of Uncle Horace—"Go West and grow up with the country."—*Idaho Messenger.*

CALIFORNIA IRON AND STEEL COMPANY.

WORKS, HOTALING, PLACER CO., CAL., U. S. A. OFFICES, 402 FRONT ST., SAN FRANCISCO, CAL.

TESTIMONIALS.

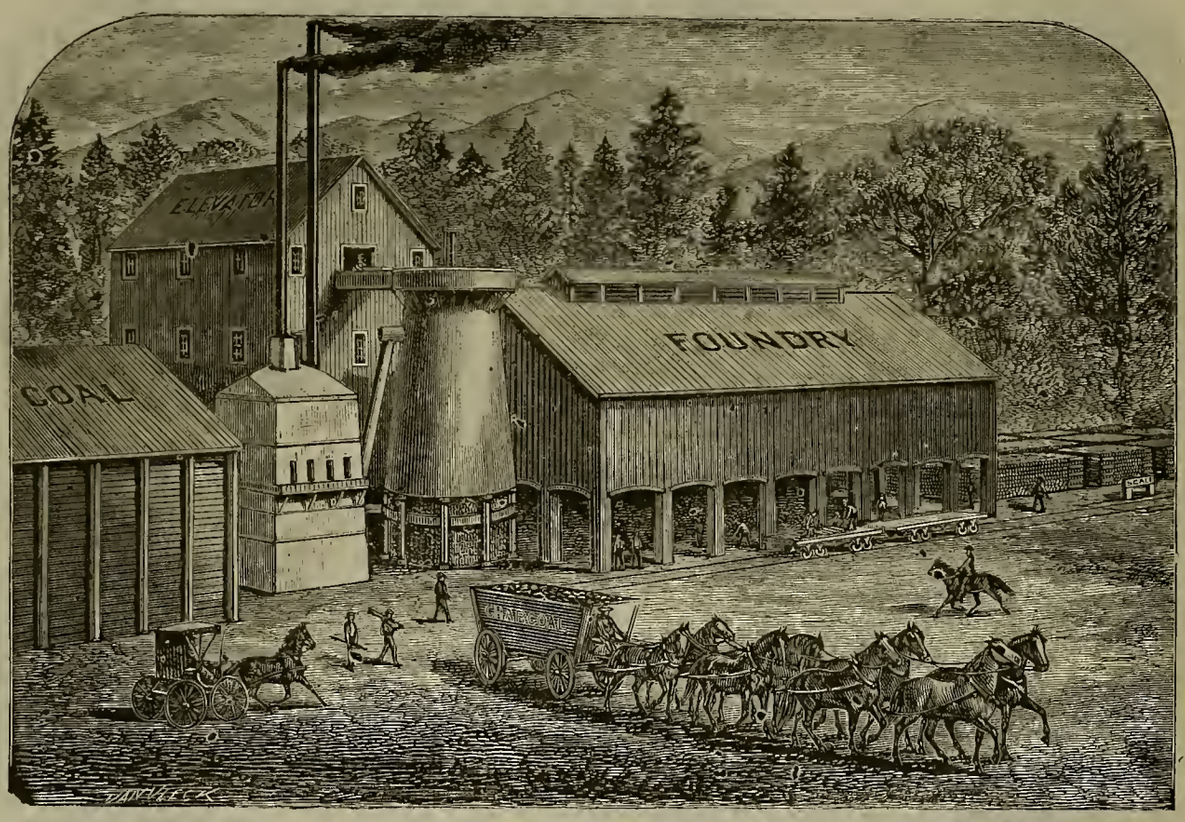
OFFICE INDUSTRIAL IRON WORKS,
San Francisco, March 7, 1882.
California Iron and Steel Company: Gents—We have used Nos. 1 and 2 of the California Iron Company's iron, and find same first-class in every respect, especially for castings that require great strength.
McCORMICK, LEWIS & Co.

OFFICE GOLDEN STATE AND MINERS' IRON WORKS, San Francisco, March 8, 1882.
California Iron and Steel Co.: We have been using your Clipper Gap pig iron quite freely for some months, and find it an excellent iron for miscellaneous machine work. In itself close-grained and tough, when mixed with Scotch iron it makes the casting of even texture, easily worked, yet strong.
We judge it to be a first-class American iron. Some experiments of ours show it to be remarkable for its chilling qualities, suggesting its value for car-wheels. Truly yours,
GOLDEN STATE AND MINERS' IRON WORKS.
By Walt L. Palmer, President.

Office ÆTNA IRON WORKS, S. F., M'ch 7, '82.
California Iron and Steel Co.: Gents—We have used a large quantity of the California Iron and Steel Company's Clipper Gap iron. We consider it a first-class iron, and for strength equal to any in this market.
PENDERGAST, SMITH & Co.

Office OCCIDENTAL FOUNDRY,
San Francisco, March 8, 1882
California Iron and Steel Co.: Gents—We have used about 200 tons of the California Iron and Steel Company's Clipper Gap iron, and for general foundry purposes find it an excellent iron, equal, if not superior, to any in this market. Yours respectfully,
STEIGER & KERR.

Office MECHANICS' FOUNDRY,
San Francisco, March 7, 1882.
California Iron and Steel Co.: Gentlemen—We take pleasure in stating, that having used considerable of your iron, we find the soft variety (to which we confined our wants), to be of excellent strength and texture, replacing advantageously similar brands of Eastern and foreign irons.
We are especially gratified in being able to state this, and congratulate you on your success, as we feel assured from the well-known conservative character of the individual owners of your company, that, with the largely increased production, for which you are preparing for the near future, you will be able to establish a uniform grade of prices, at such reasonable figures as will enable the iron founders of this city to compete successfully for much work that is now being driven from this city owing to the great and very irregular fluctuations in the price of imported irons.
Respectfully yours,
MECHANICS' FOUNDRY.



Office PACIFIC IRON WORKS, S. F., March 3, 1882.
California Iron and Steel Co.: Cents—We have used several hundred tons of your Clipper Gap iron during the past four months, and regard it as of excellent quality. It is finer in texture and stronger than any brand of English iron that comes to this market, and fully up to the average of our best American iron. Yours truly,
RANKIN, BRAYTON & Co.

Office CITY IRON WORKS, S. F., March 8, 1882.
California Iron and Steel Co.: Cents—We have used a large quantity of the California Iron Co. (Clipper Gap), and find it a very superior iron, strong and tough, and for general foundry purposes equal if not superior to any foreign iron, or iron made on this coast, in this market. The cast-iron work on the building erected for A. B. McCreery, Esq., on the corner of Pine and Davis streets, San Francisco, is made from your iron, and are the first castings ever made from California iron for that purpose.
Yours, etc., CITY IRON WORKS.

Office UNION IRON WORKS, S. F., March 8, 1882.
California Iron and Steel Co.: We have used two thousand tons of the various grades of your iron, and found it equal to the best American charcoal iron, and far superior to any foreign brands. It is tough, clean and soft—just the iron for machine purposes. PRESCOTT, SCOTT & Co.

Office NATIONAL IRON WORKS, S. F., March 8, 1882.
California Iron and Steel Co.: Gentlemen—We have used Nos. 1 and 2 iron of your make, Clipper Cap, and have found it a very strong iron, giving us entire satisfaction.
Respectfully yours, MARSHUTZ & CANTRELL.

Good Land and Sure Crops.

There has been steady and tolerably rapid advancement made in the growth of a majority of the towns in Colusa, Butte, Tehama and Shasta counties. Especially is this so in the agricultural districts where the land produces at least fair crops in all seasons—wet or dry—as does the land on the Reading Ranch. Those looking for homes in California where diversified farming will pay every year; where wood and water are plenty and easy to be obtained, and other desirable advantages are to be had, should address the proprietor of the Reading Grant.

Some 14,000 out of 26,000 acres of the grant remain to sale at comparatively low rates, in quantities to suit purchasers, on easy terms. Prices range from $5 to $30 per acre. The tract is between two and three miles wide, with the Northern Division of the C. P. R. R. passing centrally through its entire length. Send postage stamp for free circulars containing information about Shasta County and these lands, to the proprietor of Reading Ranch. EDWARD FRISBIE,

Anderson, Shasta County, Cal.

VIGORIT POWDER.

NO ACCIDENT HAS EVER HAPPENED.

ALL POWDERS manufactured by the California Vigorit Powder Co. are SUBMITTED during the course of manufacture TO SCIENTIFIC and accurate TESTS for safety and strength.

They are tested for Safety against Friction, Fire, a Temperature of 212° Fahr., and the various shocks to which Powder is liable in practical handling.

The following qualities are common to all grades of Powder manufactured by the Company:

Safety; Non-Leakage; Freedom from Noxious Gases; Uniformity and Strength.

If consumers desire it, the EXACT STRENGTH of any Powder shipped to them will be GIVEN IN FOOT POUNDS.
☞ Send for Pamphlet showing methods of testing the different qualities of all Powders.
The Company manufactures:

DETONITE.

This is an explosive involving new principles and recently patented. It is the **Strongest Powder ever placed on the Market**, in this country or abroad. It is the **Safest Strong Powder ever made.** For very refractory rock this Powder is the most economical in the market.

VIGORIT, No. 1, XX.

This Powder is **Stronger than the Highest Grades of Hercules or Giant.** It is only surpassed by "Detonite." It is suitable for hard rock.

VIGORIT, No. 1.

For general work this Powder has no superior. It has the advantage over Giant, Hercules or Vulcan in safety and freedom from noxious fumes.

VIGORIT, No. 2.

Equal to any correeponding Grade in the Market.

LOW POWDER.

VIGORIT, L. P.

This is a Powder suitable for **Bank Blasting, Log Splitting** or the work generally in which Black Powder can be used. It is STRONGER THAN BLACK POWDER, having from twice to ten times the effective strength, depending on resistance. It is **Smoother to Judson Powder,** in being more sensitive to the cap and more convenient in handling.

Best Qualities of FUSE and CAPS sold at Lowest Rates.

Of the Forms of Minerals—Imitative Forms.

The researches of Graham and others have shown that inorganic matter may exist in two perfectly distinct conditions, known respectively as crystalloid and colloid. The same portion of matter may be at one time crystalloid and another colloid, the difference being one of condition not of composition. Thus rock-crystal consists of crystalloid silica, but if a fragment be powdered, fused with carbonate of soda, dissolved in water, and precipitated by hydrochloric acid, the precipitated silica will now be in the colloid state. When in solution, crystalloids differ from colloids in some very important particulars, and on passing into the solid form the differences are still more evident.

Colloid minerals are few in number. They are totally devoid of cleavage or distinct internal structure, but they usually break with a very perfect conchoidal fracture. They occasionally, but not often, occur in what are called imitative forms, but are usually amorphous or without definite external forms. As examples of true colloid minerals, we may mention opal and obsidian.

Crystalloid minerals are very numerous, they include, indeed, the great majority of mineral species. They may be either crystallized, crystalline, or crypto-crystalline.

Crystallized minerals are those which occur in definite geometrical forms. Ordinary rock-crystal is a perfect example of crystallized mineral.

Crystalline minerals are such as have the peculiar internal structure observed in those which are crystallized. They consist, indeed, of a multitude of crystals confusedly crowded together, so that the external geometrical form is lost or disguised. The cavities or "vughs" of such aggregates, however, often display distinct crystals. The kind of quartz known as cross-course spar affords a good example of a crystallized mineral.

Crypto-crystalline minerals are those in which the crystalline structure is so minute that it is not ordinarily observable, but it may be detected in suitably prepared specimens when examined under the microscope. Chalcedony and agate are good examples of crypto-crystalline minerals.

Many crystalline and crypto-crystalline, and some amorphous minerals, occur in what are known as imitative forms. The chief of these are the following:

Globular. This form is often seen in wavellite, prehnite, and other minerals. On breaking a globular mineral, it is almost always seen to be composed of a multitude of indistinct crystals radiating from the center, and sometimes the outside of the sphere is roughened by the projecting points of these crystals. Occasionally the true crystal form of these terminations may be observed, but usually they are indistinct.

Reniform (kidney-shaped). This form is not unfrequently met with in nodules of iron pyrites, or other minerals which occur imbedded in clay or mud. Some kinds of red and brown hematite are called kidney iron from their occurrence in this form.

Botryoidal (grape-like). This form is often seen in that kind of chalcopyrite known as blistered copper ore.

Mammillary. This form is often seen in malachite and blistered copper ore.

Coralloidal. This structure is observable in chalcedony and aragonite, especially in specimens from Styria. It sometimes occurs in connection with earthy deposits of iron ore, when it is called flos-ferri, or the flower of iron.

Cone in cone. This structure is often met with in iron ores from the coal measures. It consists of a series of fibrous concentric conical masses, the points of the cones meeting together, or sometimes interlaced.

Stalactitic (icicle-shaped). Chalcedony, calcite, and barytes often occur in this form. Sometimes the stalactites are hollow, sometimes solid; but in stalactites of calcite and barytes, a cross-section almost always reveals a structure consisting of fibres radiating from the center, and the same thing is visible in properly prepared slices of chalcedony, when examined under the microscope.

It is probable that most, if not all, of the above-described imitative forms are the result of deposition from solution, at any rate this is known to be the case in some instances. Thus, stalactites of calcite, or carbonate of lime, may be seen in process of formation in caverns in most limestone districts, and they are very frequently formed under bridges or tunnels which have been built with lime mortar. The process of formation is as follows: Rain water containing carbonic acid in solution in filtering through limestone, mortar, or other material containing carbonate of lime dissolves a part of it. On becoming again exposed to the air drop by drop, part of the carbonic acid is given off, part of the water evaporates, and part of the carbonate of lime is deposited. A stalactite once formed, the water naturally descends to its lower end before falling off, and it is there that the greatest amount of carbonate of lime will be deposited, and in this direction its growth will be most rapid, although a small quantity of solid matter will continue to be deposited on the sides of the stalactite, so producing the concentric structure shown in the vertical section of a stalactite, or in the cross-section. The radial structure appears to be of later origin; it is really due to an incipient crystallization set up within the mass.

The water dropping from the stalactite will still contain some carbonate of lime in solution. This will be deposited on the ground beneath, when the conditions are favorable, forming what is known as stalagmite. A cross-section of stalagmite, however, will differ from that of a stalactite, owing to the tendency which the drops of water have to spread themselves out. If the supply of water be abundant, a sheet of stalagmite will be formed if only a little falls, a pillar of stalagmite will gradually rise towards the stalactite above; but in all cases the separate layers will be of about equal thickness throughout.

The crystalline structure sometimes observable in the imitative forms already described, is probably the result of a secondary action of the crystallizing forces, following the actual formation of the solid mineral. There are, however, other imitative forms which are merely irregular crystals or crystalline aggregates, and in the formation of which the crystallizing forces appear to have been concerned from the first. These are the so-called capillary and wiry forms observable in native silver, the mossy and leafy forms seen in native copper, the dendritic markings of oxide of manganese, the reticulate groupings characteristic of mountain leather, and the stellate groups of crystals often met with in stilbite and other minerals.

Mining Explosions and Mining Warnings.

The meteorologist who is at the trouble of giving warnings in the daily and other papers showing atmospherical changes that may affect mining operations, calls our attention to the result of last year's explosions, and we certainly agree with him that the small loss of life last year is matter for congratulation, considering the number of persons who were convicted of offensee, some of which were calculated to lead to serious consequences. The warnings appeared to be based on the action of the barometer. High barometric pressure, we are told, accompanied 22 of the occurrences, and low pressure 15. This, to some extent, would go to prove what we have often pointed out, that the barometer was not a reliable instrument as regards sudden changes of the atmosphere likely to influence gases in mines; that is, to indicate them before they really take place, and not coincident with them. Of the three heaviest explosions last year those at Whitfield and Lilydale took place at the time of highest barometer, and that at the Abram colliery with a low barometer. As to atmospheric pressure in connection with the explosions of last year, they go to support the theory that the most dangerous time is when the barometer is high. And we are told by Mr. Thompson, of Manchester, as the result of an extended period of observation as to explosions, that "the gas in the pits spoke out loud and clear long before any change could be discerned in the mercurial barometer." A careful collation of these atmospherical changes is by no means satisfactory as to their probable cause. The Government Inspector for Derbyshire, Mr. Evans, gives 16 non-fatal explosions in his district in 1880; and with respect to them he says: "It is curious to note that eight of them occurred whilst the barometer was rising, four whilst it was steady, and four when it was falling." Mr. Dobson, a high authority, considers that an altogether erroneous value was attached to a low barometer, for the explosion might be deferred until the storm had entirely passed away, and the mercury had regained the light and stability peculiar to settled weather. On the other hand, we have the views of Messrs. Scott and Galloway, from observations made extending over a period of four years, and they found that during that time 54% of the explosions occurred from a fall of barometer, 1% from a rise of thermometer and 27% from causes associated with atmospherical influence. The barometer has been looked upon as an instrument for indicating the changing conditions of the atmosphere, and indicating approaching liability to explosions in coal mines. But many of our ablest mining engineers do not consider it to be reliable, for changes take place before they are recorded. One of these gentlemen informs us that it has been found that in whatever degree the mercurial column may move, before that movement is perceptible the gas will have made its movement to the equivalent of such movement, and that instead of being an indicator of what is taking place in a mine as regards the exudation of gas, the barometer was only an indicator of what had taken place before its movements are perceptible.

But pressure is, of course, the great element for consideration. Gas exists in coal under considerable pressure, and no sooner is the mineral cut into than it liberates a considerable quantity of the gas, whether the barometer is high or low; but if there could be brought to bear on the face of the coal pressure equal to the gas escaping from it, there would be no escape at all. It has been held that the aqueous vapor in a mine, small though it may be, and consisting of two atoms of hydrogen and one of oxygen, may play an important part in forming the materials necessary for an explosion. When the air at a low temperature is taken into a mine, the aqueous vapor seizes with avidity the coal and gases, until in a very short time, the mixture may be at an explosive point. To bring the gas up to an explosive point, there is another important element contributing to it in an atmosphere of low temperature—that is, when temperature is low, the aqueous vapor occupies a much less space and the atoms of oxygen are much nearer together, so that, space for space, under such conditions a less amount of gas will bring the mixture to an explosive point. So it is that in winter there is a keener gas, with a top on the flame, that will fire before it is half the length it will show in warmer seasons. Operatives vary a good deal as to the indications shown by the barometer being as quick as could be desired, but it is known that when coal falls or is cut into the gas is liberated, no matter what the state of the barometer may be. But, as a rule, as soon as there is a movement in the barometer, high or low, then the pressure on the space or pores through which the gas escapes is either less or greater, so that the quantity of gas will be determined by the variation. It has generally been considered that explosions took place with a falling barometer, but now it has been ascertained that many of these fatalities have taken place when the barometer was rising. With such interesting data as have been presented to us, in addition to our previous knowledge with respect to atmospheric influences in connection with explosions in mines, there is no doubt that the question of high pressure will receive more attention on the part of meteorologists in connection with its influence upon the existence of gas in mines. It would not, under any circumstances, be desirable to do away with the barometer at our mines, but at the same time, too much reliance should not be placed upon it, but all known precautions taken to prevent accumulation of gas. This can be most effectually done by sweeping all the working places with copious supplies of fresh air, and so long as this is done, there can be no accumulation of gas, and consequently no explosive mixtures. A mine manager should have no reason for consulting the barometer or thermometer, for it is his duty, strictly laid down by act of Parliament, to provide sufficient ventilation to dilute and render harmless all gases throughout a mine, and so long as he does that he need have no fear of an explosion.—*London Mining Journal.*

A Prospector's Ruse.

How to Head Off Claim Jumpers.

If a prospector escapes the Indians and wild beasts and other natural evils in New Mexico, he is likely to live long enough to fall a victim to the incompleteness of the mining laws there. One of them, who has had considerable experience there since leaving this country a year ago, writes from Socorro county: Every class of society has its freebooters, or those who try to make their living from the labor of others, and in no case are they more numerous than in mining regions. First among these, and the most annoying and persistent, is the claim jumper. Too indolent to hunt up mining claims for himself, and locate them in a proper and legal way, he seeks to take advantage and steal the property of others through some flaw or technicality. Very few miners ever have a legal survey of their claims, or until patent is applied for on them, and the claim jumper takes advantage of this circumstance, and when the original locator comes around to look after his claim that has been jumped, the jumper will say: "Was your claim surveyed?" "No." "Then how can you prove that your claim was located on this ground?" The United States land laws specify that the identity of claims should be fixed by reference in the location notice to some fixed natural object, or some thing by which the location may be identified, but this point locators generally neglect; and herein is the stronghold of the jumper. To head off this class of thieves, I have adopted the following plan, which I give for the benefit of any other locator who may wish to adopt it. When I make a location I write out three notices, one for record, one for posting conspicuously on the land (for which purpose it should be written on a board or, better, on a piece of zinc with a lead pencil, the chemical combination formed by the plumbago and zinc being such that the action of the weather will never efface it), and a third copy on paper, which I place in a tin can (an old oyster can will do), and after closing it up as tight as possible bury the can on the lead where it won't be likely to be dug up, and known only to the locator. The reference to some natural object should also be made, but as this can hardly ever be exact enough in description to identify a claim, if jumped, the buried notice can thus be dug up in the presence of witnesses, which ought to furnish sufficient additional evidence to convince any jury of the proper ownership of the property. This is to head off the petty thieves. In all the country acquired from Mexico under the treaty of Guadaloupe Hidalgo, there is another class who are trying to steal the discoveries of the miners by the wholesale, through the agency of lapsed or fraudulent Mexican land grants. This class can only be headed off by proper Congressional legislation, and the miners have confidence in the wisdom and honor of our present Congress that they will pass a law for that purpose and forever settle this vexed question for the future, which has been such a great drawback to our prosperity in the past.

The Wood River, Idaho, *Times* says that lately a snowslide came down Mayflower gulch, at Bullion, and buried the dwelling of Mr. Dobbins, smashing it into splinters. Mrs. Dobbins was rocking her baby at the time, and was thrown against a heavy chest, her baby under her, a heavy plank pinning her to the floor, and before the lady could be extricated the baby choked to death. Mrs. Dobbins was somewhat bruised, but otherwise uninjured.

New Mining Fan Indicator and Tell-Tale.

At a recent meeting of the Manchester Geological Society, of Wigan, Mr. Hall exhibited and explained a new fan indicator and tell-tale invented by himself. It was, he observed, most important that some automatic apparatus should be attached to all fans to indicate their speed at all hours of the day; and that, if possible, each apparatus should be so placed as to be out of the reach of any interference or tampering on the part of the officials upon whose attention to duty the instrument was intended to act as a check. He believed the presence of such an apparatus would insure greater watchfulness and care from engineers in charge of ventilating engines. The tell-tale which he had brought before them was an inexpensive and simple, yet effective method of securing this end. It could be fitted up in a few hours by any ordinary colliery mechanic, and one of these appliances had already been attached to the large Gilhal fan at the Bickershaw colliery near Wigan, where he believed it gave perfect satisfaction. The apparatus consisted of a specially designed water-gange glass, which was fixed in the manager's office, and leading from this to the fan engine-house—a distance at the Bickershaw colliery of 200 yards—was a range of three-fourth-inch iron pipes, the open end of which was placed within the fan drift; then a short branch of similar piping was joined to these, and the open end placed in the fan engine-house, where it was fixed so as to be within reach of some moving part of the engine that drove the fan, the pipe end at Bickershaw being within reach of the motion of the valve spindle.

A small lever was next attached to this pipe end, with a movement up and down, so as to open and close the outlet of the pipe, and the motion of the spindle played against this, so that at each stroke of the fan engine the pipe end is opened for an instant, and a variation in the pressure of the atmospheric air in the long branch of pipes takes place, causing the fluid of the gauge glass in the manager's office to fall to zero; but immediately the pipe end is again closed by the falling lever, the water-gange glass shows the drag on the water-gauge of the mine, and the result was a perfectly correct and constant indication of the drag of the mine, and also of the number of revolutions the fan was making. This indication taking place in the manager's office, where it could be registered in a book as often as might be convenient, was entirely out of the reach of any interference on the part of the person responsible for the speed of the fan. The fluid in the gauge glass fell to zero at each stroke, so that it was only necessary to count these movements in the glass to determine the speed of the ventilating engine, and the hight of one leg of the fluid over the other between the strokes was the measure or water-gauge of the mine. Where the fan to be indicated traveled at a great speed, each fifth stroke only was dealt with, so as to allow sufficient time to read off the drag of the mine between the indications of the speed, and this was effected by the introduction of two small wheels working at five to one, and deriving their motion from the drag crank of the engine. The cost of the apparatus did not exceed three or four pounds, unless the distance between the manager's office and the fan was very great; but so far as regarded the efficiency of the appliance, distance was immaterial, as it had been tested up to 800 yards. For those who were anxious that the indications should be permanently registered, an eight-day clock could be added, which was fitted with a revolving brass cylinder, carrying a diagram paper upon which a spiral line was drawn by a pencil, indicating the number of revolutions by the fan and the water-gauge during any and every hour of the day or night. In conclusion, Mr. Hall pointed out the advantage of a permanent and indisputable record of the state of the ventilation in the case of such occurrences as the recent explosion at the Abram collieries.

The Southern Pacific railroad is being built through Texas as rapidly as possible. Two construction gangs, consisting in all of 2,000 men, are at work; one having started from El Paso, and the other working westward from San Antonio. It is thought that these two divisions will meet at the Pasos river, which is about 130 miles from San Antonio and 400 miles from El Paso. On the El Paso end of the line over 253 miles of track have been completed, and the work is going on at the rate of about a mile and a half a day. The country is wild and mountainous; deep ravines and gulleys abound, and mountain streams run through precipitous canyons. English steel rails are used in the construction of this road, and most of the supplies are brought from San Francisco.

There are now reported 33 breaks in the levees between Huspuckana and Greenville, on the Mississippi, and terrible suffering is experienced. The steamer *Cannon*, arrived at Vicksburg Saturday. Capt. Campbell says that he rescued over 200 head of cattle, mules, etc., and a number of families from the ends of the levees, and at one place went out into a swamp about a mile and a half for 30 people who were literally starving to death.

It is claimed by local anglers that the salmon which have lately been running up the Pajaro river are not the well-known California or Sacramento river salmon, but are the land-looked salmon that were put in the Pajaro river several years ago.

A Princeton Reunion.

The second reunion of the Princeton College Association of the Pacific Coast, on the evening of the 15th inst., in San Francieco, was a very happy event to those present, recalling scenes and reminiscenoes of earlier and maturer years, which all collegians appreciate. This association, including all who spent some time in the college of New Jersey or Nassau Hall, whether graduates or not, now has on its roll 60 names of those scattered throughout the Pacific States and Territories. With regard to this college, one of the oldeet and most distinguished in the Union, now in its 136th year, a common error has prevailed among those not intimately acquainted with its history. It is oftsn confounded with the equally-noted Preshyterian Theological seminary, which is also located at Princeton, and to which many graduatss of the literary and scientific collsge go when it is their intention to enter the ministry of some Protestant denomination; for many clergy hesidee Preshyterians pass through that seminary. At the literary college, so justly celebrated in the aunale of our country from anti-revolutionary times to the present, many Catholics as well as Protestants have graduated, though its Faculty is composed of eminent ministers and laymen of the Preshyterian church. Drs. McCosh, Atwater and Cameron are dietinguished among the former class, and Profs. Arnold, Guyot and Stephen Alexander among the latter. It ehould he remembered, then, that the college and the theological seminary at Princeton are entirely separate institutions.

More than half the college association for this coast are laymen. Because of the area over which the membere of this association are scattered hut few can attend these pleasant rennione. Thirteen were present at this reunion, ae followe: Rsv. Alhert Williams, class of 1829; Judge John S. Hager, class of '36; Rev. John Edwards, '48; James F. Foulkes, M. D., '49; Maj. Harry I. Thornton, '54; Judge S. F. Bigelow, '57; J. W. A. Wright, '57; Maj. John B. Mhoon, '59; Rev. F. E. Shearer, '62; S. P. Kelly, '65; Rev. J. P. Eghert, '74; Rsv. H. H. Wikoff, '74; D. Wills, Jr., '81. Nearly half the ahove number are natives of Southern States, many Southern parents, hoth hefore and since the war, having eent their sons to Princeton collsge, or, ns it ie familiarly known, far and wide, "Nassau Hall."

The features of thie reunion were a preliminary husiness meeting, nnd an elegant dinner in private rooms of the Palace hotel. Rev. Mr. Williams is president, Major Mhoon was chosen ae secretary, and Major Thornton as a member of the executive committee.

In the husiness meeting a cheering letter was read from Dr. Jamee McCosh, now President of the college, as he hae heen since 1868, when he wae invited from Scotland to accept that position, as Dr. John Witherspoon wns just 100 years hsfore. Among other facts he gave the following numher of etudents for the last 14 echolaetic yeare, ending each Juoe: 1868, 264; 1869, 281; 1870, 328; 1871, 364; 1872, 379; 1873, 376; 1874, 417; 1875. 408; 1876, 483; 1877, 472; 1878, 496; 1879, 495; 1880, 473; 1871, 488; 1882, 537.

In 1868 there were 19 instructore, now there are 37. He hriefly eums up the couree of etudy ae embracing "the more important languagee, ancient and modern, claseical and continental, including Sanscrit and Anglo-Saxon;" and eaye that, of the Englieh language and literatnre there are three profeesore, and in the sciences thirteen, most of them pursuing, hy aid of the etudents, original researchee in astronomy, physics, chemistry, hiology, geology and physical geography. He ehowe that a new chapel, at a coet of $120,000, (the gift of a Mr. Marquard, who formerly preeented the college with a gymnaeium), will he completed hy the next commencement in June. During the last fonrteen yeare, eeveral million dollare, the donatione of individuals, have heen expeuded in the erection of firet-clase stone huildings for various purposes, so that the old collsge ie now ae thoroughly equipped in every respect as ie any institution of learning.

At the hanquet, from 8 to 11 P. M., came a true "feast of reason and flow of soul." Social converee, friendly chat, recitale of college experiencee, interepersed with mirth and jollity, prevailed. All were called on for after-dinner epeechee, and almoet every one took part in them. For the time the great and vaetly changed world of the present wae forgotten, and they lived their college days again. The memories of those present, and the information they gave, extended hack from last year to more than half a centnry.

Several epecial toasts were reeponded to as follows: "Our Alma Mater," Judge J. S. Hager; "Princeton College, as a National Ioetitutioo," J. W. A. Wright; "The South, ae a Patron of Princeton," Maj. H. I. Thornton; "Dr. McCosh, and the Faculty," Rev. J. P. Eghert; "The Princetoo Ministry," Rev. John Edwards; "The Progrese of Princeton," Rev. F. E. Shearer.

Space permite us to give only a few historical facts touching upon Princeton and Princetonians from Judge Hager's remarks. The college was first chartered in 1746. It received a second charter in 1748, and that year graduated its firet class. In 1783 Congrese met in the college buildings. Among the signers of the Declaration of Independence were three Princeton men—Richard Stockton, one of its first graduates, also Benj. Rnsh and President Witherspoon. Eight Princetonians were signere of the Articles of Confederntion, and the following eight were memhers of the Convention which adopted the Constitution of the United States: Gunning Bedford, Wm. R. Davie, J. Dayton, Wm. C. Houston, Lnther Martin, Oliver Ellsworth, James Madison and Wm. Patterson.

Princeton has furnished one President of the Uoited States, James Madison, and two Vice-Preeidents, Aaron Burr and George M. Dallas; also to Congress, 48 Senators and 116 Representatives, 27 of ite graduates heing memhers of the first National Congress. It has furniehed one Chief Justice of the U. S., Oliver Ellsworth, and six Associate Justices, viz.: Patterson, Livingston, Thompson, Johnson, Wayne and Harlan. Of its graduates, 13 have hesn U. S. District Judges, 27 Governors of States, 42 collsge Presidents, 18 Cabinet officere and 16 ministers and envoye to foreign powers. To the judiciary of our States it has contrihuted 10 Chancellore, 64 Associate Juetices and 21 Chief Justices; among the latter, Reeve, of Connecticut; Lewis, of New York; Rush, of Pennsylvania; Booth, of Delaware; Archer, of Maryland; Hutchinson, of Virginia; Nash, of North Carolina; Stone, of South Carolina; Lumpkin, of Georgia; Walker, of Alahama, and Bihh, of Kentucky.

Princeton men naturally review with pride the valuable eervices of their Alma Mater to our country at large, and the solid educational advantages it has afforded to many engaged in the various useful pursuits of life. For the convenience of any youths on the Pacific coast who may wish to enter Princeton, examinations will he held in San Francisco on the 22d and 23d of June next, at a place yet to he designatsd, and of which timely notice will he given.

J. W. A. W.

Associations of Minerals.

Some minerals occur chiefly or exclusively in granite, othere in diorites or echists, others again in limestones, or in volcanic rocks. Moreover, certain minerals are commonly associated with other minerals, forming natural groups, which in some cases appear to have heen formed contemporaneously. It is this latter kind of association which is of so great assistance to the student in enahling him to recognize minerals at sight, much as specimens of the same mineral from different localities may differ in appearance. It is to this association also that the term *paragenesis* primarily applies, hut its meaning has heen extended so as to inclnde all euch associations of minerals in groups, or of minerale which are congenial to each other, as miners say. In the following liets a few of the hetter known examples of paragenesie only are set down. We have distingnished those minerals which have heenfonnd sometimes *enclosed* in the species referred to by printing them in italics:

Quartz is associated with orthoclase, *mica, tourmaline, chlorite*, chalyhite, calcite, dolomite, harytes, fluor, *cassiterite, pyrites, chalcopyrite, limonite, hematite, gothite*, wolfram, cuprite, *copper, galena, blende*, hournonite, gold, etc.

Calcite, with *quartz, copper, chalcopyrite, pyrites*, etc.

Apatite, with hornhlende, axinite, magnetite, garnet, topaz, echorl, cassiterite, wolfram, qnartz, orthoclase.

Barytee, with galena, oalcite, hlende, chalcopyrite, pyrites, etc.

Argentite, with etephanite, arsenic, pyragyrite, etc.

Caeeiterite, with qnartz, echorl, chlorite, miepickel, pyritee, hlende, wolfram, topaz, lepidolite, etc.

Chalcopyrite, with qnartz, finor, galena, hlende, chalybite, dolomite, pyritee, calcite, etc.

Galena, with qnartz, pyrites, chalcopyrite, hlende, calcite, etc.

Pyrites, with quartz, caesiterite, chalcopyrite, galena, fluor, miepickel, limonite, cohaltite, emaltite, inverarite, etc.

Cuprite, with quartz, copper, malachite, cheeylite, fluor, etc.

Fluor, with quartz, wolfram, chlorite, orthoclase, chalyhite, calcite, etc.

Garnet, with *magnetite*, apatite, epidote, talc, mica, hornhlende, limonite, etc.

Serpentine, with steatite, diallage, aeheetoe, copper, chryeocolla, calcite, chromite and nickel ores.

Sulphur, with celeetite.

Tellurium, with gold, hismuth.

Plationm, with iridium, rhodium, palladium, etc.

Gold, with quartz, tellurium minerale, etc.

Cinnahar, with tetrahedrite, quartz, calcite, etc.

Magnetite, with chlorite, garnet, hornhlende, etc.

In the Blue Wiug eilver dietrict, eaet of Bannack, Montaoa, there are more miners at work nt the present time than there have heeo for a oumber of yeare paet. Many of the mines of that district are looking well, and are producing a good quality of ehipping ore. The Blue Wing dietrict is looming up, and the ore yield for thie winter will he of considerahle value.

All machinery and apparatus has been taken out of the Belcher helow the Sutro tunoel level. The usual amount of low grade ore is hsing extracted above that point.

In Candelaria wood selle at $16.50 and $17 a cord. Rough lumher ie delivered at $48 per 1,000 ft., and at $61 per 1,000 ft., for dreseed. Shingles are rated at $6.50 per 1,000.

Copper Mining and Smelting.

The copper interest of the conntry ie developing into one of so much importance that any substantial improvement in the appliances for reducing thie class of ores will attract general attention. The following letter from the Superintendent of the Copper Queen mine in Arizona, giving an acconnt of the operation of an improved style of emelter in use there, will he read with much intereet hy all parties in any way connected with this class of mines. There is prohahly no more promising field of mining ventnre than that now offered in copper. The consumption of this metal is increasing so rapidly that the price is constantly advancing in the face of increased production. Copper mining is a great and growing industry, and the recent development in nll the mining States and Territories are a surprise even to thoee moet familiar with the mineral resources of the conntry. It is the oninion of many well informed upon the suhject that the production of copper will in the future rival in value that of the preoious metals. There are douhtless many other mines where snccess equal to that mentioned might he made with a judicious investment of capital. There is no douht of the fact that this class of mining has so far heen immensely profitahle, and with suoh improvements in the proeese of reduction, the ohances of lose or failure, with good management, are reduced to a minimum:

OFFICE OF THE
COPPER QUEEN MINING CO.,
BISBEE, A. T., Jan. 3, 1882.

Messrs. RANKIN, BRAYTON & Co.. "Pacific Iron Worke," San Francisco, Cal—GENTS: In answer to your inquiriss for some particulars in regard to the operation of your furnaoss at the Copper Queen mine, would say, that we have had one thirty-ton smelter in hlast almost constantly since the 20th of August, 1880. The second smelter, of eame capacity, was put in hlast on the 28th day of August last, and has heen runuing ever since, without an hour'e intsrmission. We pnt through something over 30 tons of ore per day to each smeltsr, exclusive of flux, and our average hullion product from the two furnaces is from 25,000 to 27,000 pounde per day, running from 96.5 to 98 fine. Our record for the year 1881 showe a production of nearly 5,000,000 pounds hullion—the prodnct of one smelter running continuonsly, and one only four months of the year.

On acconnt of the scarcity of timhsr for making charcoal in our locality, we use coke for fuel—mostly English—though we have occasionally ussd Trinidad iu connection with it.

To illustrate the facility with which these furnaces can he managed, would etate that in several instancss, when our coke supply has hecoms short, I have hanked the fires for several days at a time and etarted the stream of hnllion again in fifteen minutes after putting on the hlast. The furnacss are adapted to any class of copper ores, are eimple in construction, easily handled, and with proper care are alwaye in order. I have had more than 20 years' experience in copper emelting, and have never eeen a furnace that can compare with yours for reliahle, effective and economical work; in fnct, I know of no other furnace now made that will handle euceessfnlly the copper ores of the Western Statee and Territories. The general character and details of the emelting plnnte furniehed hy yonr firm, I may aleo eay, are well adapted to the husinees and fnlly meet all requirements.

I make thie etatement in the general interest of the emelting hueineee of the country, and as due to your energy and enterprise in working up to euch a etate of perfection thie important hranch of mining machinery. Yonrs trnly,

LEWIS WILLIAMS,
Superintendent of Furnacee of Copper Queen Mining Company.

NOTE.—These emeltere were made from plane furniehed hy Meesre. Bishee, Williame & Co., a firm which hae heen long recognized ae the higheet authority on this coast in all mattere relating to the treatment of copper and galena ores. Tho Williame Bros. are widely known as the moet experienced and ekillfnl emelters in the country.—*Arizona Star.*

GEN. GEO. B. MCCLELLAN ie President of the Silver City M. & M. Co., of Grant county, New Mexico. Mr. Henderson ie Superintendent. Thie company hae acquired all the interests in Grant county of the late Carrolton company. The property purchaeed by the new company comprisee the etamp mill and machinery in town, the Old Timer and Volcano mines in the Silver Flat mining district, and the Camphellite, near the Coeette. They will prohably renew the negotiations which their predecessore commenced for the purchaee of eome of the claims of Frank Biehy. Some of the other officers are John B. Scott, Vice-Preeident, Wm. T. Mieereau, Treasurer, Mr. Gray and Mr. Cummings, Directore.

SUPERINTENDENT RHODES, of the Humholdt sulphur minee, telle the *Silver State* that new doposite of brimetone have have heen found in the minee receotly which are more extensive thnn any heretofore discovered. Some ten men are at work in the minee at present, and the force will he increased ae soon ae the road is in condition to haul the refined eulphur to the railroad. The new deposite will enahle the company to ehip any quantity of eulphnr during the coming enmmer.

Ores of Copper.

Copper ocnrs very ahundantly, and in a variety of forms; hut many minerals oontaining it are muoh too poor in copper to allow of its profitahle extraction, or do not occnr in sufficient haundance to permit of their olassification as oree of copper, and such aocordingly will not he noted in this place. The ores of copper occur in rocks of almost all ages, hut most ahundantly in the Lias nnd Permian formations, the lodes of Cornwall occurring in Permian and older rocks, and the oree are most frequently accompanied hy iron pyrites and qnnrtz, while in some Cornish mines fluor-spar occurs largely. The metal ocnrs in the native or metallic state, also as oxide, eulphide, carhonate, chloride, sulphate, phosphate, and silicate, etc., of copper.

Native copper is found in isolated masses, sometimes of considerahle size, in thin laminæ, or in filiform pieces, and the copper sand, or harilla occuring in Chili, consists of metallic copper in small graine, mixed with qnartz; occasionnlly a mass of copper ore will consist of carhonate of copper on the ontside, enveloping an inner layer of red oxide, itself enclosing an inner nucleus of metallic copper. Native oopper ie ductile, malleahle, and exceedingly tough; it ie usually very pure, hnt is often nccompanied hy small quantities of silver; in Chilian varieties the latter occasionally amounting to 7% or 8% of the metal. The chief localities of its occurrence in quantity are Michigan, Arizona, Brazil, Chili, Peru, Siheria, Faroe Isles, in some of the Cornish mines, also in North Wales, and in smaller quantities not unfreqnently along with other copper oree in the varions loealities of their occurrence.

The red oxide or cuprite contains, when pure, 88.78% of copper, and is found massive or granular; frequently iron-grey on the surface, hut alwaye affording its characteristic reddish-hrown streak. It ocoure at Hnel Gorland and other Cornish mines, in New Jersey and the district of Lake Superior, hut most ahnndantly in Australia.

The hlack oxide contains, when pure, 79.8% of copper, hut it is frequently very impure. It occurs in Lake Superior, in Saxony, Chili, and at the Burrn Burra mines of Australia.

Green carhonate of copper, or Malachite, contains 57% of copper, nnd is distinguished hy its fine emerald green color, with a luster inclining to resinous, and a streak of a eomewhat paler tint than the mineral in the mass. It oocurs massive in the Ural mountains, in Sonth Australia, Siheria, the United States, and South America, and incrusting other ores in most copper mines.

Azurite, Cheesylite, or hlue carhonate of copper contains 55.16% of copper, and ocours along with the green carhonate of copper in Australia, as also in Cornwall, Chessy, in France, and in the United States.

Copper pyrites, or yellow copper ore, forms the ore from which ahout five-sixths of the copper produced in Great Britain is ohtained. Its formula showe it to contain, if pnre, 34.81% of copper; hut ite average yield as prepared for sale ie only from 4% to 12%, or uenally 7% to 8% of copper. Thie ore is of a hrase-yellow color, dietingnished from iron pyrites, which it reeemhlee, hy ite inferior hardnese; it ie fonnd associated with qnartz, gneise, and clay-elate, and occure in large quantitiee in Cornwall and Devon, accompanied hy grey copper ore, galena, hlendee, copper glance, tin stone, etc.; it ocenre aleo in Sweden, Saxony, Cuha, South America, the United Statee, Anetralia, and eleewhere.

Vitreoue or grey enlphide of copper, copperglance or redrnthite and purple oopper, are enlphidee of copper occurring largely in Cornwall and elsewhere, aeeociated with hæmatite iron ores, and containing variahle proportione of eulphide of iron; a variety of the purple ore occure in the cupriferoue ehale of Manefeld, in Saxony.

Grey copper ore, fahlerz, or fahl-ore, is a steel-grey or iron-hlack, hrittle mineral, occurring hoth maeeive and crystallized in cuhic forms. It is a cuprone sulphide, in which the copper ie replaced more or lees hy iron, zinc, eilver, and mercury, along with variahle proportions of the sulphidee of antimony and areenio. The argentiferone fahl-ore contains occasionally 30% of eilver, and not more than 15% of copper; whilet others contain as much ae 48% of copper, with hut emall proportione of eilver. Gold ie also eometimee a conetituent of thie ore. Fahlore occure in Cornwall, Norway, Sweden, Hungary, the Hartz, Mexico, etc.

Chrysocolla, a hydrated eilicate of copper; and Atacamite, a hydrated oxychloride of copper, are eometimee employed for the extraction of the metal. The former occure accompnnying other copper oree in Cornwall, Saxony, Nova Scotia, Chili, Auetralia, and Lake Superior; and the latter is aleo fonnd in Chili, Auetralia, Saxony, etc.

Cupric eulphate oocure in coneiderable proportion in the watere iesning from certain copper minee, ae thoee of Amlwch, Wicklow, the Rio Tinto, and Thareie mines of Spain, etc.

THE Silver City Miners' Union have elected the following officers: G. M. Holmes, Preeident; E. Hamilton, Vice-President; H. V. Angell, Recording Secretary; George Langridge, Fioancial Secretary; Joleee Lawson, Treaeurer; A. Dickson, Conductor; J. Martin, Warden; Frank Clemente, Frank Frame, Frank Howard, George Page and D. J. Elliott, Trustees.

Recent Contributions to the California State Mining Bureau.

[Furnished for publication in the MINING AND SCIENTIFIC PRESS by HENRY G HANKS, State Mineralogist.]

[CATALOGUE.]

3657 Rhodonite and Pyroluaite—Section 14, Township 1 north, range 16 east, M. D. M., 2 miles south of Summersville, Tuolumne county, Cal. W. A. Lewis.

3658. Silver Ore—Plumosa mine, Ures district, Sonora, Mexico. F. E. Monteverde.

3659. Silver Ore—San Miguel mine, Ures district, Sonora, Mexico. F E. Monteverde.

3660. Silver Ore—Cocinera mine, Ures district, Sonora, Mexico. F. E. Monteverde.

3661. Copper Ohance—Bacamaca-l mine, Sinaloa, Mexico. F. E. Monteverde.

3662 Float Silver—Uralama mine, Alamos district, Sonora, Mexico. F. E. Monteverde.

3663. Silver Ore—Quintera mine, Alamos district, Sonora, Mexico. F. E. Monteverde.

3664. Silver Ore—Joya mine, Sinaloa, Mexico. F. E. Monteverde.

3665. Schoellto—Near Seattle, Washington Territory.

3666. Cuproschoelite with Tourmaline—Kern county, Cal.

3667. Yellow Brick—Made from the alluvial soil of the Rio Grande, which is free from iron. Cost $6 per 1,000. S. W. Holliday.

3668. Ear Ornaments—Made and worn by the natives of the East Indies Miss F. Von Lindner.

3669. Rock specimen—Of peculiar interest, which consists of alternate layers of quartzite and limestone. On the weathered surface, the limestone has been cut away, probably by the action of drifting sand, while the quarzite remains clear and sharp. This specimen is an interesting study, the question suggesting itself how the two minerals were deposited so evenly and with such alternate regularity. When found, the strata were vertical. Locality, Inyo range, 2,000 ft. above Owen's valley, Inyo county, Cal. W. W. S. D. Woolhull.

3670. Fragment of Bone of Mastodon (?)—Taken from the soil 80 ft. below the surface, Bowie station, S. P. R. R. The molars are in the museum of the California Academy of Sciences. S. W. Holliday.

3671. Globular Pyrites in Calcite—Near Auburn, Placer county, Cal. Miss F. Von Lindner.

3672. Pig Iron—First run on ores from Taxada Island iron mines. C H. Simpkins.

3673. Stream Tin—Near Parrvilla, Durango, Mexico. John B. Phillipin.

3674. Magnetite Loadstone (Natural Magnet)—Magnet Cove, Arkansas. J. Z. Davis.

3675. Piece of Tusk of Fossil Elephant—Placer county, Cal. D. C. Stone.

3676. Vein Matter, Gold Bearing—Golden Crown mine, Coulterville mining district, Mariposa county, Cal. A. W. Owen. This specimen is remarkable as showing the effect of solfataric action in the vein.

3677. Concretionary Cinnabar—Washington mine, Napa county, Cal. S. A. Coburn.

3678. Rock Specimen (Anamesite? with Section for the Microscope by Mellville Attwood—Culebra hill, Panama canal locality, Isthmus of Panama. M. Eissler.

3679. Rock Specimen (Anamesite?) with Section by Mellville Attwood—Cerro La Peta Imperador, Panama canal, Isthmus of Panama. M. Eissler.

3680. Conglomerate with Section by Mellville Attwood (Anamesite?)—Panama canal locality, Isthmus of Panama. M. Eissler.

3681. Rock Specimen (Not Determined)—Voisluage Imperador, Panama canal locality, Isthmus of Panama. M. Eissler.

3682. Rock Specimen (Not Determined)—Cerro Malo Rio, Panama canal locality, Isthmus of Panama. M. Eissler.

3683 Rock Specimen (Not Determined)—Chutes d'Obispo, Panama canal locality, Isthmus of Panama. M. Eissler.

3684. Rock Specimen (Not Determined)—Petites Chutes d'Obispo, Panama canal locality, Isthmus of Panama, M. Eissler.

3685. Rock Specimen (Not Determined)—Imperador, Clay, Panama canal locality, Isthmus of Panama. M. Eissler.

3686. Soundings—Carboe, Panama canal locality, Isthmus of Panama. M. Eissler.

3687. Coal—Isthmus of Darien. M. Eissler.

3688. Borings—Blanchet shaft, Panama canal, Isthmus of Panama. M. Eissler.

3691. Coal—Hank Mitchell's mine, 15 miles from Eureka, Eureka county, Nev. Hank Mitchell.

3692. Blue Calcite—San Diego county, Cal. W. H. Green.

3693. Rock Specimen (Not Determined)—Cut into cube and polished. Spanish Park canyon, Utah county, Utah. J. W. Hood.

3694. Silver Ore—Penobscot mine, 25 miles from Helena, Montana.

3695. Wall Rock with Dendrites—Vulture mine, Yavapai county, Arizona.

3696. Rich Copper Ore—Mountain Gem mine, Genesee, Plumas county, Cal. Johnson & Bicknell.

3697. Thinolite—Desert near Volcano station, S. P. R. R., San Diego county, Cal.

3698. Small Pebbles of Pumice Stone—Colorado desert, 5 miles west of Volcano station, S. P. R. R., San Diego county, Cal.

3699. Selenite—Colorado desert, 5 miles west of Volcano station, S. P. R. R., San Diego county, Cal.

3700. Andalusite—Moore's hill, 12 miles south of Mariposa, Mariposa county, Cal. Richerd B. Thomas.

3701. Quartz and Pyrite—Both crystallized. El Dorado county, Cal. E. W. Hulford.

3702 Twenty-five Samples of Mexican Woods—F. E. Monteverde.

3703. Gold Quartz—Soulsby mine, Tuolumne county. See No. 912. John Seechman.

3704. Silver Ore—Twins mine, three miles southeast of Calistoga, Napa county, Cal. Said to assay $50 per ton. J. H. Crossman.

3705. Gold Quartz Showing Free Gold—Sheep Ranch mine, Calaveras county. Walter P. Jenney.

3706. Rose Quartz—Hope valley, Alpine county, Cal. Lewis Chalmers.

3707. Rose Quartz—Yokhe (?) valley, Tulare county, Cal. Thomas Osborn.

3708. Rose Quartz—Plumas county, Cal. H. Ergels.

3709. Iceland Spar—Darwin, Inyo county, Cal. S. D. Woodhull. This spar is nearly as fine as the true Iceland spar, and could be used for optical purposes.

3710 Quartz Crystals Doubly Terminated—Beveridge district, Inyo county, Cal. S. D. Woodhull.

3711. Chrome Iron—Michigan Bluff, Placer county, Cal. S. W. Collins.

3712. Siderite (Carbonate of Iron)—Tejunga canyon, Los Angeles county, Cal. Occurs in a quartz ledge, country rock, granitic. J. W. Redway.

3713. Silver Ore—Henrietta mine, Wagonton, nine miles from Silver City, Idaho. The face of this hoe specimen is covered with crystals of argentite(?). A. L. Simondi, assayor, Silver City, Idaho.

3714. Rich Copper Ore, Principally Cuprite—Mammoth copper mine, Mono county, Cal. J. E. Johnson.

3715. Gold Quartz—Hite mine, Hite's cove, Mariposa county, Cal., 900 level. See No. 1344. N. J. Colman.

3716. Chromic Iron—Within one mile of Auburn, Placer county, Cal. S. P. Collins.

3717. Limonite after Pyrite—Perfect crystals. Chowchilla valley, Mariposa county, Cal. Richard B. Thomas.

3718. Silver Ore (?)—Railroad mine, Los Angeles, Los Angeles county, Cal.

3719. Gold on Quartz Crystal—Beveridge district, Mono county, Cal. The gold has the appearance of having been formed in the crystal, but close inspection shows that it is cemented on the outside by oxide of iron. J. H. Holt.

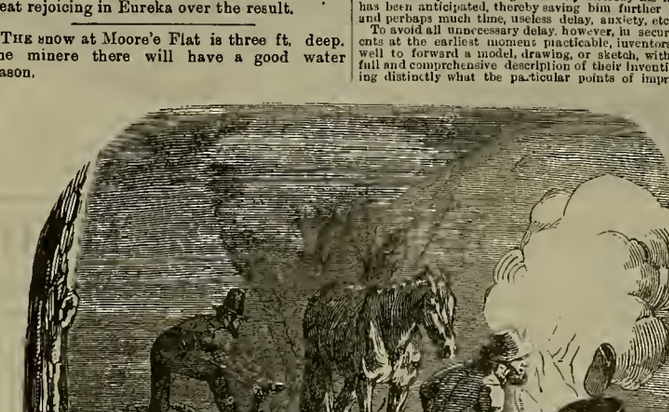
3720. Gold Quartz—Pioneer Union mine. Humbug mining district, Placer county, Cal, 300 ft. below the croppings, ledge 4½ ft. thick. E. G. Spencer.

THE mining interests in the eestern part of Churchill county, Nev., ere, according to a correspondent of the *Silver State*, brightening up, and hid fair to become reliable end valuable property. At Silver Hill, 20 miles east from Stillwater, work is being pushed on the No. 1 with a double force of men. The lode ie now exposed for 100 ft. At a depth of about 50 ft., it is in free milling ore, and assays run from $100 to $700 per ton in gold and silver. Parties from San Francisco have recently made two visits to the mine, and say that they will erect a mill on the property in the early spring. The Goodell camp, situated about 20 miles further east, is said to present most flettering prospects.

PREPARE FOR BUSINESS LIFE.—If parents would only see tn it and properly prepare their boys for business before trying to get them into business, they would save great trouble to themselves, the boys and their employers. Moreover, the boys would have some basis to begin with and to build upon, and instead of spending a year or two learning tbo rudiments and general principles, would begin active work with a knowledge of them already. If such preparation could nôt be made without great trouble and expense, there would he some excuse for people taking "green" boys around trying to get them places. But when there are such institutions as the Pacifio Bnsiness College, where a life scholarship can be had for $70, there is no reason why parents should not help the hoys out and give them a good start. There they will learn the mysteries of hook-keeping in all ite branches, learn to write well, and learn practical business details. When they leave they go prepared to he of some use to their employers, instead of a drag and a source of annoyance, as must he tbe case when everything is to be learned. The case does not admit of argument. Anyone with a boy destined for business pursuits, who negleote to give him the advantages of such an institution, if it is in his power, is responsible for the hoy's heckwardness in business, and the direct cause of his slow advancement.

THE RICHMOND-ALBION SUIT.—In the Richmond-Alhion (of Enreka) mining suit, the Supreme Court decided the St. George and Victoria patents void and reversed the judgment of the District Court. This decision virtuelly givee the Alhion company about all they claimed. According to the *Sentinel* there wes great rejoicing in Eureka over the result.

THE snow at Moore'e Flat is three ft. deep. The minere there will have a good water season.



PROSPECTORS IN CAMP.

THE EAGLE LAKE TUNNEL.—The tunnel to tap Eegle leke is being advanced at the rate of 35 ft. per week. It will he about a mile and a half long, and it is expected thet it will he completed next fall. It will furnish water power for rnnning several sew-mills, and finally will irrigate a greet area of now harren sage-hrush land in Honey Lake valley. The tapping of this lake is an experiment that is heing watched with great interest everywhere on the coast. Shonld it prove as successfnl as is anticipated, it will he followed hy a similar tapping of many other lakes on hoth sides of the Sierras, for mining, timhering end other purposes.—*Virginia Enterprise, March 17.*

THE Assooiated Pioneers of the Territorial Daye of California—a New York organizetion—has issued an appeal to California pioneers everywhere to come forward with cesh for a monument to the late John A. Sutter. Sutter was e noble Celifornian, to whom the early pioneers were deeply indehted, and to whom the United States itself owes a deht.

THE Honse Private Land Claims committee, hy a vote of five against two, decided to recommend the passage of a hill providing for the adjudicating of McGarrahan's claim to the rancho Panoche Grande, California, hy the Supreme Court of the District of Columhia, with an appeal to the Supreme Court of the United States.

THEY increased the capacity of the pumps the other dey at the Alta hy making an alteration in the pecking. Heretofore, the harrels of the pump have been stuffed to an interior diameter of 8 inches. This stuffing has been taken out, giving the harrels their full diameter of 10 inches, the poles heing packed to correspond.

ON the 17th a enowslide completely demolished the 40-stamp qnertz mill known as the "Hank's mill," in Sierra county, Nevada. The mill is situated at the hase of a precipitons mountain, and the snow coming down from above buried it.

Patent Business.

Patents Are Virtually Contracts

Between Inventors and the public. The considerstion flowing from both parties to the contract is expressly fixed by statute. The Government requires the following consideration in every case: First, that an applicant for a patent shall disclose a new and useful improvement, of which he is the first and original inventor. Second, that the invention has not been patented, or published in a printed publication, prior to the date of his *invention*. Third, that the invention has not been in public use, or on sale, more than two years prior to his application for a patent. Fourth, that the invention shall be properly described and claimed in the specification forming a part of the patent. Provided an inventor complies strictly with these conditions, the Government guarantees to at the inventor shall have the exclusive right to make, use and sell the thing invented for the term of 17 years.

The Patent Law provides that in case a patent, which is the evidence of the contract, is not executed in compliance with the requirements of the law, it may be annulled and rendered void. Hence, it is of the greatest importance to every inventor that his patent or contract be skillfully and accurately drafted, that it may afford him complete protection for his invention during the life of his patent.

Secure a Good Patent.

An inventor should first ascertain whether or not his improvement has been patented to another. This requires an exhaustive search among all the patents in the class to which the invention relates. This question can often be answered gratuitously by us immediately on receiving full information of the invention, by reason of our long and extensive practice as patent solicitors and editors and publishers of first-class scientific and industrial journals during the past 20 years and over. When the question of priority of invention is not so readily to be determined, it is generally best to make what is termed a "preliminary examination," by searching through the patent office reports among the patents in the class to which the invention relates, and referring to our extensive patent library, containing compilations of special classes of American and foreign inventions, mechanical dictionaries, scientific encyclopedias, files of scientific and mechanical newspapers, and an immense number of patent applications by inventors of the Pacific coast, carefully filed by this office since 1860.

If, by this "preliminary examination," the improvement is found to have been previously invented, our client will receive for the small fee of $5 for the examination a verbal or written report showing definitely whereby his invention has been anticipated, thereby saving him further expense, and perhaps much time, useless delay, anxiety, etc.

To avoid all unnecessary delay, however, in securing patents at the earliest moment practicable, inventors will do well to forward a model, drawing, or sketch, with a plain, full and comprehensive description of their invention (stating distinctly what the particular points of improvement are), with $15 as a first installment of fees. If the improvement appears to us to be novel and patentable, the necessary papers for an application for a patent will be prepared immediately, and forwarded to the inventor for his signature. When the inventor receives the application and finds it duly prepared, he will carefully sign and return the same plainly addressed to us, with postal money order or express receipt for our own fee. The case will then be promptly filed by us in the Patent Office, and vigorously prosecuted to secure the best patent possible. [This course is the most expeditious and satisfactory, as no time is lost in transmitting correspondence relative to the preliminary steps to be taken.] When the patent is allowed, the inventor will be duly notified, and on sending the final Government fee of $20 to us, we will order the issue of the patent, and forward the same as soon as it is secured from the Patent Office.

The payments are thus divided and made easy. We make no pretence of doing cheap work, in order to entice custom, nor do we afterward make additional charges to bring the bill up to a fair compensation. We do our work honestly and thoroughly, and we never give a case up as long as there is a chance to obtain a patent. The Agency charge is from $25 to $30, or sometimes more, if the invention is intricate or complicated, or requires much labor. Drawings cost from $5 upward, according to their number and the time employed; and, if a model is sent, the express charges upon this and the papers must be added. The total cost, in addition to Government fees, rarely exceeds $10, and for this we do all we can without appealing the case.

When the inventioo coosists of a new article of manufacture, or a new compesition, samples of the separate ingredients sufficient to make the experiment, and also of the manufactured article itself must be furnished.

Modele and Drawings

Models are now seldom required by the Commissioner of Patents, and generally ooly in intricate cases. Perfect drawings of practical working machines ere considered more satisfactory to the Patent Office than the old and more cumbersome system of storing up an immense hulk of almost numberless models.

Drawings or sketches sufficient to illustrate clearly the invention, with a sufficient description to enable us to make a full set of perfect drawings for the Patent Office is all that we require. A model will answer our purpose as well, however, in cases where the iuventor can more easily furnish it for our use.

The value and even the validity of a patent often depends on the character, clearness and sufficiooy of its drawings. There are thousands of existing patents in which the improvements are but partially or very poorly illustrated in the drawings. When an attempt is made to dispose of such patents, the vagueness and defects of the drawings often prejudice capitalists and manufacturers against the invention, while in reality it may be of great value, and would meet with ready sales had the invention been fully portrayed by artistic and skillfully executed drawings. Again, when patents of this character are brought into court, the uocertainty and ambiguity of the drawings enable the opposing experts to mystify the judges as to the construction or combination of parts intended to be covered by the patentee. In all cases prepared by us, the drawings are made under our personal supervision, by skilled draftsmen in our constant employ, and every precaution is taken that the invention is fully and clearly shown by different views, so that the improvement will be readily understood by the Examiners in the Patent Office, and comprehended by the public when the patent is granted.

In the Patent Office

The application is assigned to the Examiner having charge of the class to which the invention relates. The case must then take its turn with others in the order of filing, and in due time is carefully examined to test the novelty of the invention. If the Examiner fails to find anything that anticipates the invention, a patent is immediately allowed, provided the specification and claims are drafted in proper form. Should the Examiner find a prior patent which, in his opinion, anticipates one or more of the claims of the application, a letter of rejection is sent to the attorney in charge of the case; and if the attorney coincides with the views of the Examiner, the claims rejected are erased. In preparing applications for patents, an attorney should be careful to familiarize himself with the class of inventions to which the application pertains, so that the specification and claims may be drafted as nearly perfect in the first instance as is possible. This course saves much time in prosecuting the application to a patent.

When claims are improperly rejected on patents which do not anticipate the spirit or wording of the claims, proper steps are immediately taken to convince the Examiner of his error. This is done, in most part, by personal arguments, as the differences in construction, operation, function and results are more readily discovered and appreciated by an oral presentation of the facts than can possibly be done by relying solely on written arguments. In order that the Patent Office record of the patent shall be complete, an oral argument is generally supplemented by a manuscript brief, that others, in examining the files at any future time, may clearly comprehend the position taken by the Examiner and attorney in prosecuting the case to patent.

In addition to our own personal attention to the interests of our clients here, we have, for over 12 years past, had constantly in association with us in Washington, one of the soundest legal counselors and ablest of practitioners in patent business in this country, who carefully attends in person to our business at the Patent Office and has attained success in a most marked degree.

Perfect Claims.

The value and force of a patent are dependent on its claims. A patent may disclose to the public the most important and valuable invention, and yet the claim be of such meager scope that the patent is actually worthless. When the claims of a patent are so loosely drafted that infringers can flood the market with improvements, differing from the improvement disclosed by the patent only in slight changes in construction and arrangements of parts, such a patent is valueless to the owner, as it fails to afford him that exclusive and complete protection guaranteed by the Patent Law. Hence it is that the greatest care, skill and perseverance are required, first in properly drafting the claims in the first instance, and, second, in prosecuting the application before the Patent Office, and maintaining the rights of the inventor to claims as broad and sweeping as the invention will warrant. This latter is no easy task. The Examiners of the Patent Office serve in the capacity of attorneys guarding the interests of the public. It is their sworn duty to exercise the greatest care and watchfulness, that patentees do not secure claims of greater scope than they are justly entitled to. It is but natural that Examiners are sometimes in error as to just what scope should be accredited an invention. Although the Examiners act under honest convictions in cases where they refuse an inventor his just rights, yet it is the duty of the attorney to maintain the claims of his client, if he is convinced that they are just and proper. To succeed in this requires the display of tact, firmness and ability; and when the Examiner is made to see that the inventor is honestly and fairly entitled to the claims which have been rejected, he will almost invariably recede from his former action, and allow the case.

Advantagee to Inventore on the Pacific Coaet.

The firm of DEWEY & CO., (continuously editors and publishers of the MINING AND SCIETIFIC PRESS, nearly from its early commencement in 1860), offer comparatively far better facilities to the local inventors of the Pacific States and Territories, than are possessed by any other agents in America. Members of the firm give personal attention to the applications entrusted to their care. They have been longer in practice in patent soliciting than most agents who are still personally engaged in the business. They have secured more U. S. and forelgo patents in the past 20 years (with very few exceptions) thao any other firm still existing. Their practice has been so successful and long continued that the great majority of inventions on this side of the American continent have been patented through their agency, thus affording them great and valuable experience, by thorough information of the true principles and points of novelty in the inventions, whether general in character or peculiarly local to this coast.

The extensive business combination and experience of this firm is undoubtedly one of the most fortunate in existence for affording inventors prompt and reliable advice and the best possible facilities for securing their full patent rights with safety and dispatch at uniformly reasonable rates.

Every patentee of a worthy invention is guaranteed the gratuitous publication of a clearly stated and correct description of his invention in one or more of our influential and reliable newspapers, affording just the circulation that is best calculated to widely inform the class of readers most specially interested in the subject of his invention.

Saving of Time, Etc.

Inventors on this coast will find that owing to our familiarity with inventions and local affairs of this coast, we can more readily and fully comprehend their wants, and thus save much of the time ordinarily consumed in preliminary writing back and forth when distant agencies are employed.

Caveats.

A Caveat is a confidential communication made to the Patent Office, and is therefore filed with its secret archives. The privilege secured under a caveat is, that it entitles the caveator to receive notice, for a period of one year, of any application for a patent subsequently filed, and which is adjudged to be novel, and is likely to interfere with the invention described in the caveat, and the caveator is then required to complete his application for a patent within three months from the date of said notice. Caveat papers should be very carefully prepared. Our fee for the service varies from $10 to $20. The Government fee is $10 additional.

To enable us to prepare caveat papers, we only require a sketch and description of the invention

Rejected Applications.

Inventors who have rejected cases (prepared either by themselves, or for them by other agents), who desire to ascertain their prospects of success by further efforts, are invited to send the papers of our unrivaled facilities for securing favorable results. We have been successful in securing Letters Patent in many previously abandoned cases. Our terms are always reasonable.

Inventors who do business with us will be notified of the state of their application in the Patent Office, when it is possible for us to do so.

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. B. Haggin for Giant and Old Abe Co., Black Hills also Corliss Pumping Engines, 20x60, for Hoisting and Pumping Works, for 2,000 feet deep. **Baby Hoists for Prospecting, 4 H. P. to 6 H. P.**

Wire Rope, Safety Cages and any Size and Forms of Cars. **McCaskell's Patent Car Wheels and Axles—Best in Use.**

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois. New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail.

HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,750 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 30x36. BOILERS of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

HERCULES SLAYING THE GIANTS.

HERCULES POWDER

Derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade

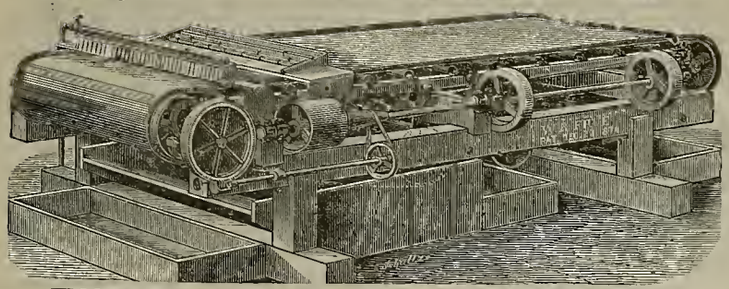
$1,000 CHALLENGE!



THE FRUE ORE CONCENTRATOR.

Nearly 300 are now in use, giving entire satisfaction. Awarded First Premium and Silver Medal at the Industrial Fair for 1880 of the Mechanics' Institute of San Francisco, Cal.

Saves from 50 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal; water required is less than in any other wet Concentrator; the power required per machine is less than one-half horse power; the labor required is light, one man on a watch can attend to sixteen machines.

We challenge any other Concentrator in use for a fair and impartial competitive trial, side by side, for stakes of $1,000 each, and we mean business.

☞A machine with all improvements can be seen in working order and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont street.

SHEET IRON PIPE.
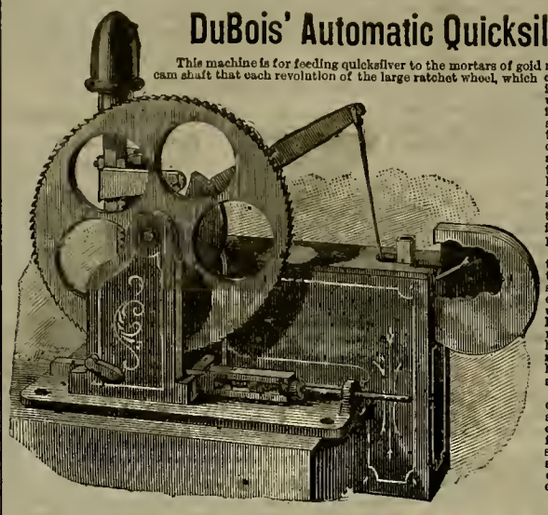
Lap-Welded Pipe, all Sizes, from Three to Six Inches. Artesian Well Pipe. Also, Galvanized Iron Boilers, from 25 to 100 Gallons.
Iron Cut, Punched, and Formed for making Pipe on ground, where required. All kinds of Tools supplied for making Pipes. Estimates given when required. Are prepared for coating all size of Pipes with a composition of Coal Tar and Asphaltum.
Office and Manufactory, 130 Beale Street, San Francisco.
SHEET IRON PIPE.

DuBois' Automatic Quicksilver Feeder.


This machine is for feeding quicksilver to the mortars of gold mills. It is so connected to the cam shaft that each revolution of the large ratchet wheel, which can be regulated to revolve once in one, two, three or four minutes, as desired, dips a small cup into a reservoir of quicksilver, and by a trip of the cam, empties the contents into a pipe leading down to the mortar, supplying an exact quantity at regular intervals, superseding the ordinary hand feeding, which is of necessity subject to great irregularity, and liable to neglect. It renders the amalgamation of all the gold in the pulp equally certain and perfect.
The mechanism to produce this depression and elevation of the cup, is driven by the cam shaft, similarly to the self-feeders, over which so much ingenuity has been expended to regulate the delivery of ore to the mortar. As it is to be desired to have the ore go in constantly and regularly, so it is equally desirable to have the mercury fed constantly and regularly.
A chief point of excellence of this machine is, that it allows the quantity of mercury which would be otherwise fed in mass, in one hour, to be subdivided into a number of small portions, and fed almost continuously; *i. e.*, from every one to four minutes.
Price, complete, $100.
For Sale by **WHITNEY & MARSHALL,** Sole Agents
22 & 24 Fremont St., San Francisco.
Dealers in Iron, Steel, Hardware and Mining Supplies, Wrought Iron Pipe and Fittings, Pump Columns, Wire Rope, etc. A large stock of Boiler, Plate and Sheet Iron of every description.

MOREY & SPERRY,
MANUFACTURERS OF
Gold and Silver Grinding and Amalgamating Machinery
HOWLAND'S PULVERIZER Takes the Place of the Cumbersome Stamp Mill and can be put up in one day ready for work.
IT HAS BEEN FULLY PROVED AND TESTED.
It weighs complete, 7,000 pounds. It costs $1,500 ready for the belt. Will crush one ton per hour of hard quartz that will pass through a 40-mesh screen. The wear is less than in the stamp mill. Its wearing parts are plain castings and can be dropped into position in a few moments, as shown by the letters A, B and C, no bolts or keys are required; it can be set upon the floor of a mill with no expense for foundations, and can be used to crush and work in charges or continuous. It will amalgamate either gold or silver ores, making a simple, cheap and effective mill, it requires twelve-horse power.

Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver ores Chloridizing Furnaces, Retorts, Rock Drills Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill supplies. Iron Work complete for Wood Frames, also
SPERRY'S WROUGHT IRON FRAME FOR STAMP MILLS.
☞Great saving in time and money over the Wood Frame. It is made complete with Wrought Iron Frame ready to put upon the foundation. We construct Mills with Stamps weighing from 350 to 900 pounds for Gold and Silver Ores. Wet or Dry Crushing Mortars.
MOREY & SPERRY—Warerooms, 92 and 94 Liberty St., N. Y.

The "OLD RELIABLE" with improvements, making it
THE MOST PERFECT TURBINE NOW IN USE.
Comprising the **Largest** and the **Smallest** Wheels, under both the **Highest** and **Lowest** head used in this country. Our new Illustrated Book sent free to those owning water power.
Those improving water power should not fail to write us for **New Prices**, before buying elsewhere. New Shops and New Machinery are provided for making this Wheel. Address
JAMES LEFFEL & CO., Springfield, Ohio, and 110 Liberty St., N. Y. City.
PARKE & LACY, Sole Agents, 21 and 23 Fremont St., S. F.

STEEL CASTINGS
FROM 1-4 TO 10,000 lbs. WEIGHT.
True to pattern, sound and solid, of unequaled strength, toughness and durability.
An invaluable substitute for forgings or cast-iron requiring three-fold strength.
Gearing of all kinds, Shoes, Dies, Hammerheads, Crossheads for Locomotives, etc.
15,000 Crank Shafts and 10,000 Gear Wheels of this Steel now running prove its superiority over other Steel Castings.
CRANK SHAFTS, SHOES, DIES and GEARING specialties.
Circulars and Price Lists free. Address
CHESTER STEEL CASTING CO.,
Works, CHESTER, Pa. 407 Library St., PHILADELPHIA

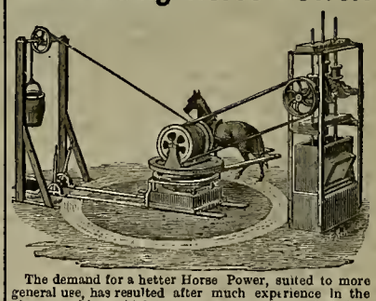
MINING ENGINEER,
Room 75, 115 Broadway, New York.
☞Agent for PADDOCK'S Ore Dressing Machinery. Mining Machinery supplied.

San Francisco Cordage Factory.
Established 1856.
Constantly on hand a full assortment of Manila Rope, Sisal Rope, Tarred Manila Rope, Hay Rope, Whale Line, etc., etc.
Extra sizes and lengths made to order on short notice
TUBBS & CO.,
611 and 613 Front Street, San Francisco

New Mining Horse Power.


The demand for a better Horse Power, suited to more general use, has resulted after much experience in the above machine, which we can recommend as a First-class Hoisting Power, under complete control of man tending bucket, through levers connecting with brake and clutch.
This power is light and strong, so that two or more horses can be used for crushing ore or other work.
C. H. BAKER,
Agent and Manufacturer of Mining Machinery

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

From the official list of U. S. Patents in DEWEY & Co.'s SCIENTIFIC PRESS PATENT AGENCY, No. 252 Market St., S. F.

FOR THE WEEK ENDING MARCH 7, 1882.

254 762—ELECTRIC LAMP REGULATOR—Brewer & Waterhouse, Sacramento, Cal.

254,532 - CUTTER AND PUNCH ATTACHMENT FOR ANVILS—Geo. T. Childs, Lookout, Cal.

254,473—ROPE CLAMP—John Gates, Portland, Or.

254,552—DRAFT ADJUSTING DEVICE FOR HARNESS—Jas. Hugill, Woodbridge, Cal.

254,687—BUSHING FOR BARRELS—Thos. J. Loftus, Sacramento, Cal.

254,675—AMALGAMATOR—A. McKellar, Washington Ter.

254,760—BAN MATTRESS—J. N. Young, Sacramento, Cal.

FOR THE WEEK ENDING MARCH 14, 1882.

254,908—CAR TRUCK—A. A., E. & H. Blackman, Snohomish, W. T.

254,861—TOOL HANDLE—Thos. Bolton, S. F.

254,805- QUARTZ MILL—Jas. Day, S. F.

254 878—TAAIN BOATS—Wm. J. Little, Stockton, Cal.

254,996—HUB—A. McKellar, Fort Douglas, Utah.

254,885 —TAUCA AND DAAALOA—Alex. Rohinson, Benicia, Cal.

255,031.—TELEPHONE EXCHANGE CIRCUIT AND APPARATUS—John I. Sabin, S. F.

254,892.—WELL BORING APPARATUS—Frank Whelan, S. F., Cal.

254,858.—GRAIN SEPARATOR—David Young, Stockton, Cal.

254,815.—LIFTING JACK—Chas. Gracey, Contention, A. T.

255,052.—SAFETY LAMP—Tingry & Siffait, Portland, Oregon.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast Inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are wortby of special mention:

DRAFT-ADJUSTING DEVICE FOR HARNESS.—James Hugill, Woodbridge, San Joaqnin county. This invention relates to an improved draft-adjnsting device for barness, and it consists of a metallic end, into which the tugs or draft straps are fixed, and which has a spring-actuating sliding block near its front end. Through a hole in the front of the end piece, or box which is attached to the tng, a bar passes vertically and has its ends bent at right angles, so as to be secured to one side of the hames, which fits upon the collar. The bar is notched upon its front side, and the spring-block pressing against its rear side forces tho notches against corresponding projections on the front of the box, so as to hold the bar at any desired point. By pressing the bar back, so as to release the notches, the tug may be moved np or down, and will thus change the draft to snit.

TRAIN BOAT.—Wm. J. Little, Stockton. No. 254,878. Dated March 14, 1882. The object of this invention is to provide a boat capable of navigating shallow waters. In low rivers in which the channel is tortuous it is impossible to use a single long boat, because it cannot follow the turns of the stream. It is therefore necessary to obtain the requisite length, while still making provision for the windings of the stream. For this purpose a train of short boats is made, each one being capable of turning independently, thus causing the whole line to adapt itself to the windings of the channel. The invention consists in providing supplemental rudders pivoted to each side of the rear ends of the boat sections, so that said rudders oover the space intervening between the sections of the boat and prevent a rush of water in between them when the train boat is in motion. The snpplemental rudders also aid the main rudder in eteering when reqnired.

WELL-BORING APPARATUS.—Frank Whelan, S. F. Dated March 14, 1882. No. 254,892. This invention, relating to well-boring apparatus, consists of a supplemental tool holder, so constructed and arranged as to operate in connection with a rod, or series of jointed rods, which extend from the top to the bottom of the tube or well, the lower joint or length being made square, or so formed as to receive and steady the clasps or guides from a short supplemental tool holder, which slips down on one side of the main rod, and a wire, or other flexible connection, from its upper end, by which it may be suspended or drawn up with the tool, without disturbing or removing the main rod. The latch is operated by suitable connection, so as to be detached when it is desired to draw the tool up; and, by a peculiar device, the tool-holder is always turned so as to fit the shank in the proper position. This tool-holding device can be utilized either in drilling or boring of wells, or as a tool clamp or drill-rod grab.

CUTTER AND PUNCH ATTACHMENT FOR ANVILS.—Geo. T. Childs, Lookout, Inyo county, Cal. This invention relates to that class of anvils designed to hold cutters or punches to be operated upon by the smith's hammer, wherein a bracket having a hollow head is provided with a tool-holding shank, to which is seonred a cross-head, and beneath which are coil springs. The object of the invention is to provide a means for readily removing the tool-holding shank from the head of the bracket, and it oonsists in a braoket provided with a hollow head for the reception of a tool-bolding shank, cross-head and springs, combined with a removable securing plate, whereby the tool-holding shank can he removed and replaced with facility.

COMBINED TRUCK AND DERRICK.—Alexander Robinson, Benicia. No. 254,885. Dated March 14, 1882. This invention relates to a combined truck and derrick, the object of which is to combine in one device both the lifting and carrying capacity, for convenience in removing weights and heavy bodies of all kinds. It consists in the employment of two separate trucks connected by the derrick timbers, which, by being binged at the top, adapt the truck to separate or approach. This is accomplished by appropriate pulleys or oords. The trucks are separated on each side of a weight, and, by their approach, lift the weight between them and up on to their tops.

TOOL HANDLE.—Thos. Bolton, S. F. No. 254,861. Dated March 14, 1882. This invention relates to the attachment of small metallic tools and instruments to a holder or stock. The holder has a peculiarly-placed notch formed across it and the tool has a curved and flattened elastic tang to fit into this socket, the tool being thus held in place.

News in Brief.

Two colonies, says the Helena, M. T., *Independent*, one from Salt Lake and the other from Oregon, will settle at the head of Flathead lake, M. T.

THE Garfield Monument Committee has collected $106,000, of which $70,000 was given by the city of Cleveland. The sum of $250,000 altogether is wanted.

THE Los Angeles *Times* quotes the opinion of "a good judge of the value of things," to the effect that lands have advanced 25% since the recent heavy rains.

THE town of Truckee is so buried in snow that the smaller buildings are ont of sight, and a person can walk from the street directly over the roofs of most of them.

THE Tucson, A. T., *Star* says that during the late snow storm, while the S. P. R. R. Co. was building its road through Paisano pass, 30 horses died of pneumonia.

JAS. H. GAGER, an old pioneer, and for some years past Confidential Secretary for James C. Flood, died last week. He was the first Secretary of the S. F. Stock Board.

NEVADA stock men predict that the coming spring will be an excellent one for grass. The ground is well soaked with water. There is plenty of snow in the mountains.

M. E. DICKSON, of Chicago, has started for Washington with a petition for the pardon of Sergeant Mason. The petition is 2,400 ft. long, and is said to contain 120,000 names.

BRADLAUGH has been urgently pressed by a committee of free thinkers to accept the Presidency of the International Congress which is proposed to be held at Rome next autumn.

THE Chico *Record* says the coming season bids fair to be the liveliest one the lumber region in that county has ever witnessed. Preparations will shortly be made for starting up in all the camps.

NOTWITHSTANDING Vacaville is one of the greatest fruit-shipping points in the State, there has been a greater number of new orchards and vineyards planted this season than all the old ones put together.

WARRANTS were issued for 600 violators of the Sunday law in San Francisco on Monday. This included saloon keepers, cigar dealers, grocerymen, news dealers and people in many other branches of business.

HERR RULF, of Merveil, Prussia, writes the *Jewish World*, saying that the decision of the St. Petersburg Commission on the Jewish question may have the immediate effect of depriving a million people of their homes.

Pleasure in Recommending, Etc.

CARDALE, Stanislaus Co., Cal., March 6, 1882.

Messrs. Dewey & Co.—DEAR SIRS:—I hereby acknowledge receipt of patent with copies, for which please accept my sincere thanks. I shall take pleasure in recommending your agency when I have an opportunity.

Yours Truly, J. M. NELSON.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

G. W. MCGREW—Santa Clara county.
M. P. OWEN—Santa Cruz county.
B. W. CROWELL, San Benito and Monterey counties.
J. W. A. WRIGHT—Merced, Tulare and Kern counties.
JARMN C. HOAG—California.

Sewing Machines.

Several first-class styles, good as new, will be sold at a bargain. Call on or address H. F. D., at this office.

Cylinder Printing Press for Sale.

A large cylinder Hoe printing press, for country newspaper work, can be bought cheap by addressing

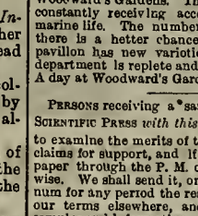
Press, Box 2361, S. F.

Business Offices and Sunny Rooms to Let.

We have some desirable rooms to let adjoining the offices of this paper which will be rented on favorable terms. Stair entrance, No. 252 Market St. Elevator, No. 12 Front St. Parties wishing offices, etc., will do well to call and see them. DEWEY & CO.

Canvassing Agents.

We want several canvassing agents who will make it their business to solicit subscriptions and advertising for our first-class progressive newspapers. Men of ability and experience can secure good pay and permanent employment. Send references and state your past occupation, etc., to the publishers of this paper.



Dewey & Co.'s Patent Agency and Newspaper Offices.

Dewey & Co.'s Patent Agency and the business offices of the Mining and Scientific Press, Pacific Rural Press, Pacific Statee Watchman and the Fraternal Record are now orahly situated at No. 252 Market Street. Elevator entrance, *No. 12 Front St., S. F.*

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased and there is a better chance to study their actions. The pavilion has new variotics of performances. The floral department is replete and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

PERSONS receiving a sample copy of the MINING AND SCIENTIFIC PRESS *with this notice marked*, are requested to examine the merits of the same, and consider fairly its claims for support, and if consistent, subscribe for the paper through the P. M. or agent delivering it, or otherwise. We shall send it, on trial, at the rate of $4 per annum for any period the reader may wish. Please notice our terms elsewhere, and if desired, send for further samples and information. Those who can circulate this No. further to our advantage are invited to do so.

BOUND VOLUMES OF THE PRESS.—We have a few sets of the back files of the MINING AND SCIENTIFIC PRESS which we will sell for $3 per (half-yearly) volume. In cloth and rather binding, $5. These volumes, complete, are scarce and valuable for future reference and library use.

CORRESPONDENCE on mining and other subjects represented by this journal is solicited from all reliable sources. Send us information, early and often, if ever so brief.

BY TELEPHONE.—Subscribers, advertisers and other patrons of this office can address orders, or make appointments with the proprietors or agents by telephone, as we are connected with the central system in San Francisco.

THE State Mining Bureau, No. 212 Sutter street, is open to the public from 10 o'clock A. M., to 5 o'clock P. M daily, (Sundays excepted). Henry G. Hanks, State Mineralogist.

A TURNED LEAF will point out the article supposed to be of special interest to persons receiving sample copies of this paper.

San Francisco Metal Market.

Patent Agency.

[ESTABLISHED 1860.]

Inventors on tbe Pacifio Coast will find it greatly to their advantage to consnlt this old experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection witb our editorial, scientifio and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors hy other Agencies. The information accnmulated throngh long and careful practice before the Office, and the freqnent examination of Patents already granted, for the purpose of determining the patentability of inventions bronght before us, enables ns often to give advice which will save inventors the expense of applying for Patents npon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 252 Market St., S. F.

OUR MOTTO IS:

Accuracy, Dispatch and Reaeonable Chargee.

JOINT FOR SHEET METAL PIPE.

RE-ISSUE PATENT NO. 8,214 TO JOSEPH MOORE AND FRANCIS SMITH.

"The Invention consists in connecting the meeting ends of the pipes firmly together and placing a band or tube around the outside of the meeting ends, which is larger in diameter than the pipes, and wlich is long enough to extend a distance on each side of the joint and then filling the space between the outside band or tube and the pipe, with a packing of lead or other soft material, either hy casting or tamping."—(Extract for specification of Patent).

These joints have been tested for 8 years, and are undoubtedly the best joint made for sheet-iron pipes—THE BEST AND CHEAPEST.

ANY INFRINGEMENT WILL BE PROSECUTED.

Mammoths.

Giant Forms of Extinct Animal Life.

Mammoth remains are among the very earliest forms of extinct animal life which attracted the attention of observers of our earth and its natural products. Theophrastus, 312 years before Christ, first recorded elephant bones as being dug from the earth in Greece, and 400 years later Pliny noticed the same fact in Italy. Both of these naturalists, penetrated by the spirit of their times, considered them as *lusus naturæ*, formed in the soil where they occurred by some plastic force of nature, and never having really been parts of living creatures.

Later on—in the 17th century—mammoth bones were found in many parts of central Europe and Italy and discussed by the philosophers of the time, who usually recognized their elephantine character, but accounted for their origin by referring them to the Noachian deluge or, in some districts, to the elephants brought by Hannibal from Africa in his invasion of the Roman Empire. A few still adhered to the *lusus naturæ* theory. Thus, in 1696, the skeleton of a mammoth was dug up at Tonna, near Gotha, in Germany, and was described by William Ernest Tentzel, a teacher in the Gotha gymnasium. He declared the bones to be the remains of an animal that had lived long before. The medical faculty, in Gotha, however, examined carefully these actual bones—saw their condyles, articular surfaces, trochanters and nerve foramina—and then decided officially that this specimen was only a freak of nature, an imitation by mineral matter working beneath the earth, of an organized creature which once roamed on the surface.

It remained for the great Cuvier to dispel this darkness and uncertainty and to throw the light of scientific study and intelligent induction upon the question of the

Nature of these Fossils.

In January, 1796, he announced to the French Institute that his examinations had shown him that these were the remains of fossil elephants, and that they were, furthermore, of species different from any now living on the globe. He says: "This idea has opened to me views entirely new concerning the theory of the earth." From that time the study of the mammoth and of its congener, the mastodon, went on upon a sound basis, and discoveries were made in great numbers and from all directions. It was soon found that the whole continent of Europe, from France and England to the Ural mountains, and from Sicily to northern Russia, was thickly strewn with mammoth bones in its alluvial and post-pliocene deposits, while those of the mastodon occurred in the pliocene proper and in the island of Malta in the miocene. Further research showed the mammoth in India, Persia, Siam, all northern Siberia, China and Japan. In both the continents of Europe and of Asia, these remains were found to be more sparsely distributed in the southern lands, and to abound in vast numbers on the northern limit, showing thus a strange disagreement in distribution with the elephant of the present day, which is confined, in its wild state, to the tropical portions of Africa and to the equally hot countries of India, Sumatra and Borneo. All the northern shore of Siberia, particularly in the deltas of the Lena and the Yenessei and in the islands lying off their coast, is crowded thick with the leg-bones, tusks and molar teeth of these extinct mammoths. In some places the combined action of sea waves and river freshets have piled these bones together in quantities so vast that their number and volume is something almost incredible. This is particularly the case at the Loichovian isles, north of the mouth of the river Seva. The tusks are here so numerous, and are in a state of such excellent preservation, that they form an important article of commerce, and are annually shipped in large quantities to Russia and to England, there to be employed by the ivory turner in the same works as is the living ivory of Asia and Africa. The preservation in Siberia of these countless large bones has long been a wonder to the inhabitants of these countries who had no reasonable explanation of their source or origin. With an absurd credulity they attributed them to a gigantic mole, which, they thought, burrowed in the ground, living on roots, and only appearing at the surface during the darkest nights. To this creature they gave

The Name of Mammoth,

Which, in their language, is a name applied to any burrowing animal. This name has been universally accepted in Europe, but limited to the species studied by Cuvier and described by his friend Blumenbach as *Elephas primigenius*. Bones of this species abound in nearly every part of Europe, although as we have just noticed, the strange fact exists that they become less and less abundant as we approach southern lands—the present home of the race. In short, the Mammoth was once an inhabitant of north temperate and frigid zones; now its descendants, reduced in numbers and degenerate in size, inhabit the tropics. Its remains occur in the Eastern hemisphere, chiefly in beds of gravel, clay and other material of post-pliocene age. In the extreme north they have still a further *situs*.

More than a Hundred Years Ago,

Not only their ivory but their carcasses were known to exist in Siberia, imbedded in solid ice. The first discovery was on the border of the Alaseia river, which flows into the Arctic ocean, in lat. 72°, or 6° north of the Arctic circle. The body, largely imbedded in ice, was still standing erect, and was almost perfect. The skin remained in place, and the hair and fur were still attached in spots. In 1772 the body of a perfect two-horned rhinoceros, covered with hair, was found preserved in frozen gravel near the Wiljui, a tributary of the Lena, in lat. 64°. The head and feet of this animal were brought to St. Petersburg; but as they had been largely divested of their skin covering, the report of their excellent preservation, as of that of the first-

Iowa Hill District.

Drift and Quartz Mines.

Editors Press:—The cold and snow have prevented us from getting much water so far for hydraulic purposes, and, consequently, many of us miners are out of employment. So youre truly concluded to send you a few lines regarding what is and has been done in our drift and quartz mines. To commence at the old

Mountain Gate Mine.

They have for some time been making preparations to put in a Liffell turbine wheel, which was made especially for the company, it being 8⅝ inches in diameter, and to work under 40 ft. head; supply pipe, 15 inches. Their old wheel was not put in by men of experience. It was almost impossible to get a millwright in the mine 6,000 ft. from the mouth of the tunnel—damp and poor light, etc. The company, too, had been prospecting so long, they could not afford to pay extra wages, and they undertook to put in their machinery with what ability they had within the company. The result was, to use the expression of an old member of the company: "It cost enough to be silver-plated all over." The new wheel was missent, and did not get to the mine until the snow set in, and it has been found impossible to get it delivered to date, as there is from 3 to 4 ft. of snow on the ridge. As soon as they get a good hoisting and pumping rig in, they expect to take out pay in the old-time style; though it always seemed to your correspondent that there was more to do then there was brains to do it, considering the amount of perverse humanity a manager had to contend with in the shape of shareholders, who did not know much about anything.

On Humbug Canyon,

Some half-mile west of the Mountain Gate mine, very fine quartz has been found in what was formerly known as the Pioneer quartz company's claim. This consists of different locations consolidated, for which they hold United States patent. It was found difficult to get supplies in through the winter, and work was suspended on the coming of the first winter storms. A large quantity of rock has been crushed from this mine. Several years ago, some of their tunnels on the east were run, when black powder was as high as $20 per keg. The claim is 6,000 feet long, and is held in ten shares. I understand they intend to continue their developments as soon as winter is over. Lower down on this canyon is the

Poole Quartz Mine.

On which was put a five-stamp mill. Their ledge got broken up in the face of the tunnel late in the fall. It was followed below the grade, and found to pay about $25 per ton. Not having time to make any arrangements for drainage, they also suspended operations for the winter. Some think this is an extension of the Pioneer-Union ledge, as the first-mentioned ledge is now called. Both of these ledges average thirty inches in width. There has been much prospecting done in the vicinity of these ledges, with varying results. Quartz is very plenty in that vicinity. The country rock is slate, and hills steep, consequently all prospecting can be done by tunnel, which can be run from $4 to $6 per foot, and is considered by many to be a favorable place to find gold-bearing quartz. As we travel

Down the Divide

To the right or "North Fork" side, we come to the Colfax Co.'s tunnel, which has been run some 1,100 ft. across a flat toward the main hill. It passes through some very similar gravel to that being worked in the Mountain Gate mine; nor could I understand why the Colfax Co. did not extract some of this same gravel.

A little further down the ridge to the left is the West Damascus Co.'s hoisting and pumping works, which have been shut down, pending the settlement of the estate of the principal owner, who died some time since. His death was quite a loss to this community. He had means, and the courage to use them. Had he lived, it is conceded many developments would have been made. The great want here is capital, judiciously expended. This mine was opened by a shaft, as it is located in a flat head of the north branch of Short Tail canyon, expecting to find a continuation of the pay channel, which the Mt. Gate Co. have. So far they have not been successful. Again, on the "North Fork" side, adjoining the Colfax, is the Pioneer gravel. They have done some prospecting, but are all poor men and unable to push their tunnel ahead. The location is considered by many as a favorable one, and that it was the outlet from the main channel which made Green Valley and Haden Hill so rich. We next come to the

Giant Gap Claim,

So called, I presume, from the immense slide which appears to have been carried from the top of the ridge into the North Fork of the American, some 1,500 ft. below. This work is being done by capital from the "Hub." Tunnel in 1,500 ft. and incline raised some 130 ft. Favorable looking gravel was found, though many think the course of the tunnel was not the correct one; that pay was passed to the north or left hand side. They are making connection with some old workings for air after which they will run for the main channel. Much energy has been displayed in this claim. It is the general wish that their efforts may be successful as, should a good mine be opened, it will be a strong inducement to other capitalists. There are several

Other Locations in this Vicinity.

But very little work has been done on them. The Mohawk company, about a mile down the "Ridge," an incline has been sunk 220 feet, as near as I can learn; but only one drift, some 80 feet in length, has been run from the bottom of the incline; work was then suspended, for reasons best known to those then in charge. Yet for the amount spent to get bottom, a single drift of that length into a hill one and a half to two miles wide, would seem like child's play. The next claim down-ridge to the left, or Short Tail canyon side, is on

Succor Flat.

This flat has been worked more or less since 1852. The two principal claims being worked now are the Copper Bottom and Succor Flat. The front was what is called "spotted." Occasionally a 4 to 6-ounce piece would be found, and again the gravel was poor. The latter company had extended their works to the foot of the hill, or back part of the flat, when they lost the rock. An incline was run some 30 feet, and good pay found. Though they could make fair wages, working up to their waists in water, they concluded it would not last long, and started a lower tunnel. This was about 1862, when no high explosives were in use, and very stiff rock was encountered. Assessments came in so frequent, many of the company moved off. The claim lay idle for several years, until another company undertook to relocate it. They, however, found a good chance for a lawsuit, and gave up. The old company then went to work with a will, and it is now being worked with good judgment, and considerable gold has been taken out in the last three years; one piece of gold taken out about 18 months ago coined $1,203. Several other large nuggets have been found. Everything connected with the mine has been put in with a view to permanency. About 25 men are employed. Horses are used to run the cars. In the tunnel very little water is encountered. The workings are 2,000 ft. from tunnel mouth, where they find the bedrock has commenced to pitch to the N. W. There are many other locations in this district which would make subject for another communication, if you think this worth inserting in your interesting paper.

Yours, etc., Miner.

Iowa Hill, Placer Co., Cal., March 20, 1882.

"Talk Up Your Camp!"

Ketchum, Idaho.

Editors Press:—As you request all who are in a mining camp to "talk it up," I will give you a few points that you can put in proper form for publication. As "Wood River" has generally been talked of away from here, particular locations, save a few, have been passed by. Of this locality, which is quite in the center of Wood River mining district, but very little outside has been said. It is located 20 miles up the river from the great Snake River valley, and 30 miles from the dividing summit of Wood River mountains on the northwest and the Salmon River valley, where the famous Sawtooth Mountain mines are. It is also at the confluence of Warm Spring stream and canyon and the well-known old Indian Trail Creek canyon. The town site is on a beautiful level bench of fine gravelly land, well adapted for the purpose, and is laid off in one plat a half mile square, and subdivided in blocks and lots. It is only a two-year-old town, and is quite thickly settled. The houses are quite neat and substantial.

The ores from East Fork, Elk Horn creek, Trail creek, Lake creek, Eagle creek, North Fork, Bowlder creek, Gresnhorn creek, Warm Spring canyon mines, and all its tributaries, as well as all the ores from the well-known Smoky Mountain mines at the head of Warm Springs canyon, have all got to come here for treatment or shipping.

At each of the above-named places are many locations, and to speak of one better than the other would be doing much injustice to the owner.

I have been here some six months, and to select one location as preferable for a mine I could not, as all locations have mineral. Some of them, at the commencement of shafting or working on the vein, have more than others; but which will hold out the longest, work and time only can tell.

The general formation I should call *rockite*, as it all looks like it to me, of one kind or the other, and the age is somewhere from the commencement of creation to the present time; and the definition given by Webster of argentiferous galena applies quite well to the ores on Wood River, containing an assay value of an average of 100 ounces silver, and 50% lead. I do not know of any amount of ore in place being valued less than 50 ounces silver and 50% lead, while some run into the thousands; and further in the rock, or ground, than has been dug no one has yet seen, consequently cannot truthfully tell what we have.

Over the mountains named, in the Sawtooth mountain mines, we find free-milling silver ore, of about the same average value end in large quantities. A large number of mines have been already located there.

What we are in want of now is men of capital and ability to come to this country to work the mines; we have a plenty of them, and good and safe enough for investment of any amount of capital in any judicious way, by mining, milling, or smelting, or all combined. The mines are favorably located for all of the above. Ore in abundance, water and wood to supply all wants and to spare, also iron ore and lime for fluxes.

Transportation by railroad to this place will be in order by next September, and, until that time, we have good stages, which make close time connections with U. P. R. R. at Black Fort, and C. P. R. R. at Kelton, and only 30 hours in doing it. Freighting by the "prairie schooners" is here done in a systematic way and on time, either fast or slow, as you want the rate to be, which, in any case, is not unreasonable.

Men of capital and energy, we appeal to you to give us a visit this summer, and prove to yourselves we are telling you the truth.

J. Miller.

Ketchum, Idaho, March 16.

Copper Mines in California.

Renewed attention was given to copper mining in California about seven years ago, by the discovery of some extensive outcroppings in Nevada county, which led to the organization of the San Francisco Copper Co., with a capital of 50,000 shares. The enterprise has, according to the *Bulletin*, been carefully and economically conducted, and although the property's improvements and running expenses have necessarily been large, amounting, perhaps, to $275,000, stockholders have not been called upon to pay in over $45,000, the remainder coming out of the earnings. The business has now reached a point where it is more than self-supporting, and the first dividend, at the rate of five cents per share, was declared on the 17th, and will be paid on the 20th. Seven years is a long time to wait for returns on capital, but the confidence of the promotere of this enterprise has been equal to the undertaking, and it is to be hoped that they will be abundantly rewarded for creating a new resource to this State.

The S. F. Copper Co. has a large quantity of low-grade copper ore. This is manufactured into copper cement. The process is slow, months being required in roasting and leaching, but the works are extensive, and the product of late has been about 40 tons copper cement per month. This cement is mostly shipped to the East by rail. It contains from 85% to 87½% pure copper, and selle about 2½ cents per lb. less than refined bars. It is used for the manufacture of blnestone, and for copper paint. No adequate attempt has been made by the company to manufacture pig copper. The ore carries a good deal of sulphur, which some day may be utilized in the manufacture of sulphuric acid. Our local manufacturers of this article now pay $30 per ton for Japan sulphur for this purpose. It is thought sulphur could be made from the ores at a cost of $18 or $20 per ton, after the erection of suitable works. The ore also carries considerable iron, which is claimed to be the best in the world for the manufacture of Bessemer steel. At present the iron and sulphur count for nothing in the business of the company.

There are some other copper mines in the State, but only one that is doing much. But it is believed that more deposits of copper ore exist here. Whether they will be developed very soon is another thing. Nothing can be successfully accomplished without smelting works for the manufacture of bar copper. If we had such an enterprise, there is no doubt it would be well supplied with ore, and would pay fair interest on the outlay. During the neglect of copper mining in this State, Arizona has come to the front as a producer of this metal on a large scale.—*Nevada Transcript.*

Father of Hydraulic Mining.

A telegram from Auburn, Placer county, says: "R. R. Craig, father of ex-Senator Joseph Craig and Lee D. Craig, of San Francisco, died Wednesday at the residence of E. L. Craig, in this place. Mr. Craig was the original inventor of the hydraulic process of mining and the Little Giant and Monitor machines."

There are some errors in the above, as the *Transcript* is prepared to establish by numerous witnesses. In April, 1852, C. H. Seymour, of this city, made for a Frenchman named Chabot, mining on Buckeye hill, near town, a hose four or five inches in diameter and between 35 and 40 ft. long to convey water into the claim. It had no nozzle, but, by pressing together the end, it was found to be very useful in washing the dirt picked down from the bank of gravel, and also in cleaning the bedrock. In 1853, E. E. Matteson and his partners, at Mr. Matteson's suggestion, attached a nozzle to a similar hose, and, by directing the stream against the bank of their mine at American Hill, found that a great saving of labor could be effected. That is the history of the origin of hydraulic mining in a nutshell, and the honors of the discovery and application really should be divided between Messrs. Chabot and Matteson.—*Nevada Transcript.*

Improved Telephonic Apparatus for Mines.

The transmitters in which more than one carbon contact is used have hitherto been, for the most part, made by attaching blocks of carbon to an elastic diaphragm, with connecting bars or rockers of carbon resting freely on and between these blocks, which bars are sensitive to the vibrations conveyed by the diaphragm. In these the diaphragm is a recipient of the sound waves. Mr. E. J. Paterson, of Finsbury, Park-road, proposes to dispense with the diaphragm and use several carbon blocks, of which one or more are fixed firmly to a base and electrically connected to one pole of a battery, while he supports the remainder elastically from a fixed base, connecting them with the other pole of the battery. Or in some cases he supports all the blocks elastically from a fixed base. These various blocks he connects with one another by means of carbon rockers, and the sound waves to be transmitted will impinge directly on the carbons without the intervention of a diaphragm. Thus, without disturbing their arrangement, *inter se*, the moving carbons will be vibrated, and, acting on a current passing through the instrument, will produce the so-called undulatory state necessary to the reproduction of similar and equal vibrations in a diaphragm at the receiving end with the assistance of electro-magnetic action.

Again, most carbon transmitters of this class are constructed with the diaphragm placed sloping; by this means there is a variation of incidence of the carbon rockers on their bearings, some pressing with more dead weight than others. The object of this is that, as the acoustic waves produced by articulate speech are complex, some being of less and some of greater amplitude, it is necessary to have the various channels through which the current passes proportioned to these various factors, and this is the case when some press heavily and some lightly on their bearings, the lighter rocking easily and others less easily. Mr. Paterson proposes to obtain this variation by using carbon rockers of different gauges, and therefore of different weights, and by this means he avoids the necessity for setting them on the incline, but can use them in either a horizontal or an upright position. This allows of economy and convenience in manufacture, and affords facilities in practical use. Various dispositions of the carbon blocks may be adopted; thus, for example, a simple and efficient arrangement is that in which one block is mounted elastically on end tension wires between two parallel fixed blocks, and these blocks are connected together by two sets of four rockers of varying gauge or diameter. Again, the middle block may be the center of a group of fixed blocks, and connected with them by rockers arranged radially around the elastically supported block, which block may either be carried by tension wires or supported by a central wire. From these examples it will be seen that the instrument is susceptible of various modifications in its arrangement, the principle of construction being nevertheless strictly maintained.

Mining vs. Stock Gambling.

There is considerable difference in mining in the mountains and in stock boards. The latter is generally carried on in New York and San Francisco; the former where the metal is found. Mining in stock boards is a risky business, and is one of the greatest evils honest mining has to contend against. There is no doubt but what most of the discredit excited against mining has its birth in the wild schemes carried through by these boards. The Chicago *Mining Review*, referring to these two kinds of mining, says:

"There appears to be a feeling on the part of a certain class of journals which live in the atmosphere of the stock boards, that when a break comes and the stock exchanges are dull and deserted, that the foundations of mining are threatened, and that the strong hands in mountain fastness and desert plain, wielding pick and drill, are paralyzed by the wild speculations of one party or the other in financial centers where the exchanges exist.

"Mining for precious and useful metals throughout the length and breadth of the land is unconscious of the mimic pandemonium which is daily witnessed, where it would seem that the mines were being tossed to and fro like fallen leaves in the autumn winds. The thundering crash of the stamp mill in the land, like the ponderous footsteps of a giant, crushing mountains beneath his mighty feet, and steady stream of bullion, like a molten river of treasure, flowing from the flumes and smelters from Maine to California, drowns the tiny conflicts of the exchanges as the rolling thunder and the hurricane of the tempest hush the twitter of the sparrow. They have but a faint conception of the grandeur and magnificence even of the mining industry of the present, which is only the seed-time and harvest compared to what it will be in the future, who fear that a few brokers, in any or every city, by shouting out the price of stock, with the names of mines attached, can wake the eternal slumber of the mountains reaching to heaven, and change one particle of the treasure they hold in rocky vaults in their bosoms, waiting to be unlocked and given up to the demand of a world's industries."

The *Citizen* says that Tucson's pressing need is a smelter of large capacity for custom work.

MECHANICAL PROGRESS.

Tinkering.

An unfortunate weakness of some in charge of machinery is a desire to be constantly tinkering at it, under the mistaken impression that they are improving its performance. The reverse is the truth oftener than otherwise. With new engines and machines, it sometimes happens that the parts chafe a little through some oversight in fitting up, and require to be eased, but when it comes to resetting valves and general overhauling, though there may be instances where it is required, in most cases it is a mistake to attempt it.

Here and there, perhaps, a little slide-valve engine has been set cold, so that when it gets to work hot, the valve does not work properly; but most automatic engines, we might doubtless say all, have been correctly set by the indicator before being out of the shop, and no one can correct their performance by merely guessing at what is going on in the cylinder, and assuming that the performance can be improved by shifting the eccentrics hap-hazard.

Engines which require the fewest repairs are those that have had the least tinkering done upon them, and that, as a rule, applies all over. It is the same in the machine shop; some are eternally on hand terms with their lathes, or shapers, or planers. We recall one man who was so often upon his knees about his lathe and had so many quarrels with its performance, that he gained a nickname which stood in lieu of his proper one, and after all his fussing with his lead-screw, and feed-gear, and cone-pulley, and hearings, he did the poorest work in the shop. Perhaps because he was a tinker.

It is a good thing to know when a machine is in order, and to keep it so; in other words, "let well enough alone."—*The Wood Worker.*

Steam-Cylinder Lubricator.

At the late Frankfurt exhibition, Mr. Joseph Patrick obtained a bronze medal for his steam-cylinder lubricator, which is especially interesting, as its action depends upon a new application of the unequal expansion of two metals, or, correctly speaking, alloys. The lubricator consists of a gun-metal cup, containing a second cup, also of gun-metal, held by a conical rim. The latter is provided with a number of small holes in order to afford communication between the inside of the second cup and the annular space between the two cups, thus equalizing the pressure or vacuum, as the case may be. The two cups are held together by a cover screwed on the outer one, this cover being provided with an air-tight compartment in order to prevent condensation in case the lubricators are exposed to the cold as in locomotives. The bottom of the inner cup is provided with a conical hole closed by a steel plug which will rise from its seat as soon as steam is admitted, the gun-metal expanding in a greater degree than the steel. A passage for the oil is thus afforded, varying in size according to the temperature of the steam. When the apparatus cools, the plug again closes the orifice, thus preventing all waste of oil when the engine is not at work. In case the hole should become stopped, the steel plug will force out the foreign substance as soon as the metals contract. As an additional precaution, a strainer is placed near the bottom of the cup, to prevent impurities entering with the oil. The lubricator cannot freeze while in action, even in the coldest weather, as the space between the two cups is filled with steam. If the flow of oil be too small, the plug should be slightly screwed upward; and if too large it should be screwed downward. This can be done with an ordinary turnscrew, if necessary, while the engine is running, and oil may be supplied at any time. The great advantages of this lubricator are that the consumption of oil can be regulated to a nicety; it operates without condensation, wick, springs, valves or taps; and there are no working parts to wear out, or fine holes to become stopped.

AMERICAN VS. ENGLISH STEEL.—It was but a short time ago when English blacksmiths in this country could not find any good in American steel. They would not work anything but English steel. When given anything which they suspected to be American steel they were sure to spoil it and were loud in their protestations against it. But in time manufacturers found that American steel was of satisfactory quality the moment its origin was disguised by being provided with English marks. All this has long been outgrown. American steel stands upon its own merits to-day and is everywhere regarded superior for many purposes to its English rival. At present it is even shipped to England and is being used in large quantities in the very districts where once the prejudice was hottest against it.—*Blacksmith and Wheelwright.*

HIGH BOILER PRESSURE.—According to the *Moniteur Industriel*, Messrs. Imbert Freres, of St. Chamond, are making an iron boiler, to be tested to 100 kilos. per centimeter, or 1,420 lbs. per square inch, which is 10 times the testing pressure of ordinary boilers, and more than double that of any boiler made hitherto. The plates are one and one-eighth to one and one-half inches thick, and as this makes it impossible to rivet them, Messrs. Imbert Bros. have welded them by special machinery they possess. It is not stated what purpose this boiler is intended for.

Setting the Valve of an Engine.

My method of setting the valve of an engine is as follows:

Before the cover is put on the steam chest I disconnect the eccentric rod and take a piece of very thin tin and put in the port and move the valve up against it. I then take a sharp-pointed tram, that will reach from some fixed point on the steam-chest, where I have made a fine prick-punch mark to any convenient part of the valve stem, and there make another prick-punch mark; then I put the tin in the opposite port and move the valve against it, and then with the tram in the same point on steam chest make another prick-punch mark on the stem. When this is done I put on the cover and connect the eccentric rod.

To find when the crank is on the exact center, I bring the cross head to within about half an inch of the end of its travel. I take a pair of dividers, and from a point on the cross head I strike a segment of a circle on the guides, and before moving the engine I make a tram that will reach from the floor or wall to the fly wheel, and make a mark on the wheel. I then move the engine in the direction that it is to run, until the cross head has passed the end of its travel and returned to a point where the dividers will again intersect with the segment already made on the guides. I then with my tram make another mark on the fly wheel, and just midway between the marks I make a prick-punch mark as a dead-center mark, and then repeat the operation at the opposite end of the guides. The next move is to bring the fly wheel to a point so that the point of the tram will just enter the dead-center mark, and the crank is on its exact center.

I then take the tram that I used to mark off the valve stem and place the point of tram in the punch mark on steam chest, and make a mark on the valve stem; then move the fly wheel until the other dead-center mark is reached, and again mark the valve stem.

Then compare the marks on the valve stem with the punch marks, and lengthen or shorten the eccentric rod as the case may be, to bring them to an equal distance from the punch marks. If more or less lead is desired move the eccentric, and, to see that you have just what you want, place the tram in the center on steam chest, and compare the point with the prick mark, and the difference will be the lead, if the difference is between the center marks, for if outside it would show that the valve covered.

In all cases move the engine in the direction that it is to run, and if by accident it is moved by the dead-center mark, it must be backed up far enough, so that when you move forward again all lost motion will be taken up before reaching the mark.—*H. Reynolds, in American Machinist.*

FRICTION MACHINERY.—The operation of friction machinery has now become a fixed fact, and its easy adaptability where waste power can be utilized is a marked feature. A machine of this kind has come into use, which consists simply of an iron cylinder one foot long and one foot in diameter, having a fixed plate of hardened iron in one end, and a second plate attached to a revolving shaft, which presses lightly or closely upon the fixed plate, as circumstances require. The cylinder is filled with water, the shaft revolves, and from the friction of the plates, the water in an incredibly short time is heated, and by means of steam pipes, can be carried to great distances for heating purposes. The machine is so constructed as to render it easily adapted to all places where there is waste power, as in mills, factories, public buildings, cars, etc. The power required for its operation is very slight; thus, to carry a machine with 36 square inches of friction plates—the ordinary size—one-horse power only is required, while a machine with 225 square inches of friction surface will require, at most, but six-horse power.

ERECTING WROUGHT-IRON CHIMNEYS.—At the Pennsylvania Steel Works, at Harrisburg, they have a good plan of erecting the casings of fire-brick hot-air stoves and wrought-iron chimneys. Two new blast furnaces are erecting there, with six Whitewell stoves, 18 ft. in diameter, 60 ft. high. Instead of putting the *bottom* plates of the stove together on the ground and building the rings up from bottom to top, they commence with the *top* plates, and top ring of the stove. They are first erected on the ground and riveted and calked complete; then with three very large screw-jacks, having a lift of about six ft., and placed at equal distances around the site of the stove, worked by men with winch handles, this first ring is carefully and evenly lifted high enough to enable the workmen to put on the next ring of the plates, five ft. deep. This ring also riveted and calked complete, then another ring is added and lifted, and so on until the whole stove is completed. The wrought-iron chimney, 175 ft. high, for working these stoves, was erected in the same way.—*American Manufacturer.*

THE work on the Yale-Savon branch of the Canadian Pacific Railway is progressing rapidly. The total expenditure to the end of the year's work was $1,900,000. It is reported that a syndicate of California and Eastern capitalists is formed to build the railway from Esquimalt to North Island, taking land as remuneration.

SCIENTIFIC PROGRESS.

SCIENCE OF PERFUMES.—By a process known as inflenrage, which is the exposure of beef fat to fresh flowers in close boxes until it is thoroughly permeated and charged with their odors, the perfumes of six flowers are obtained, which could in no other manner known to science be preserved apart from the fresh petals. Those flowers are violet, jasmine, tuberose, rose, orange flower and cassie (cinnamon flower). From those six there are 50 or more combinations made for the simulation of the odors of other flowers. Sweet pea is made with jasmine and orange flower; hyacinth is counterfeited by jasmine and tuberose; lily of the valley by violet and tuberose. But the resources of the perfumer are by no means confined to the pomades, as the scented fats are termed. He uses many essential oils, the principal of which are sandal wood, bergamot, lemon, rosemary, neroli (made from bitter orange flowers), patchouli and ottar of roses. It is very difficult to get the last-named in a pure state, because its great cost tempts to dishonest adulteration. Very often rose-geranium oil is substituted for it. Musk is another important ingredient, entering, as it does, into almost all perfumes, except those which are actually imitations of flower odors, or, as styled by perfumers, "natural," as, for instance, heliotrope, tuberose, white rose and violet.—*Boston Herald.*

THE COLOR OF WATER.—Mr. Boas recently described a number of experiments on the color of water, some of which were qualitative, sunlight being sent through water in a zinc tube about 46 ft. long, closed with glass plates. Distilled water thus gave a fine deep blue-green color; the red was quite gone, the yellow feeble, while the maximum brightness was in the green. Water of the Kiel supply, Germany, let no light through the length of the tube stated; with half the length, it appeared deep orange; blue and green failed. In his quantitative experiments, Mr. Boas illuminated two screens with the same light source, before which was placed red glass, or sulphate of copper solution. The light from one screen went through water in a tube; that from the other along the tube outside. Both beams were brought into a position for comparison by means of total-reflection prisms; the screens were shifted till equal brightness was reached, and from their position the coefficients of absorption could be approximately inferred.

ELECTRICITY AND METALLURGY.—The *Cote Libre* relates the following interesting experiment made by Mr. Siemens in the presence of the members of the late Electric Congress. A number of broken pieces of steel were put in a suitably arranged crucible, with a perforated lid to it. The two currents of the electro-motor terminate in the upper and the lower part of the crucible. In fourteen minutes the entire mass of metal was heated, turned red, and liquefied. There was not a single bubble in the mass. The cost of fuel required for this apparatus is very much less than that which would be wanted if the fusion were effected by the direct application of the heat. A considerable saving may consequently be effected in steel works if this proceeding can be generally applied. It appears that the fitting up of the apparatus involves little or no difficulty.

PLANETS AND SUN SPOTS.—Adolph Duponchel has presented a communication to the French Academy upon the agreement of the increase of the frequency of sun spots with the increased action of the planets upon the sun at the time of their nearest approach to that central orb. To test his theory he ventures the prediction that there will be an increase of the mean temperature in any given place during the 12 years to come over that of the 12 years which have just passed. Uranus and Neptune are about receding from their perihelia, and he anticipates an effervescence in the solar atmosphere, analogous to that which occurred between 1716 and 1725. He thinks this solar disturbance will be accompanied with an increased number of sun spots, of which the maximum will occur, not in 1882, as is generally supposed, but between 1888 and 1892.

ACTION OF LIGHT UPON OXYGEN.—J. Dessans has contrived an apparatus for governing the admission of the radiations from a Drummond light into a jar of oxygen, and he concludes, from experiments which he has frequently repeated, that light effects a direct transformation of oxygen into ozone. In the course of his experiments he sometimes used the oxygen as pure as possible, and in other cases he introduced substances which are easily oxidizable, so that they might readily combine with the ozone. Both methods of experimenting led to the same result.—*La Nature.*

MODIFICATION OF ANÆSTHETIC METHODS.—The *Revue de Chirurgie et Arch. Med. Belge* observes that Messrs. O. de Stefanis and Vachetta, convinced of the dangers attending the use of anæsthetics—statistics showing that with chloroform there appeared one death in 2,873 cases; with ether, one in 23,204; while bichloride of ethylene showed one death in 5,000 cases—propose a modification, which has already given them excellent results, both upon men and animals.

Progress of Biology in England.

The biological section is that with which I have been most intimately associated, and with which it is, perhaps, natural that I should begin. Fifty years ago it was the general opinion that animals and plants came into existence just as we now see them. We took pleasure in their beauty; their adaptation to their habits and mode of life in many cases could not be overlooked or misunderstood. Nevertheless, the book of nature was like some richly illuminated missal, written in an unknown tongue; the graceful forms of the letters, the beauty of the coloring, excited our wonder and admiration; but of the true meaning little was known to us; indeed, we scarcely realized that there was any meaning to decipher. Now glimpses of the truth are gradually revealing themselves; we perceive that there is a reason—and in many cases we know what that reason is—for every difference in form, in size, and in color; for every bone and every feather, almost for every hair. Moreover, each problem which is solved opens out vistas, as it were, of others perhaps even more interesting. With this great change the name of our illustrious countryman, Darwin, is intimately associated, and the year 1859 will always be memorable in science as having produced his great work on "The Origin of Species." In the previous year he and Wallace had published short papers, in which they clearly state the theory of natural selection, at which they had simultaneously and independently arrived. We cannot wonder that Darwin's views should have at first excited great opposition. Nevertheless, from the first they met with powerful support, especially in this country, from Hooker, Huxley, and Herbert Spencer. The theory is based on four axioms:

"1. That no two animals or plants in nature are identical in all respects.

"2. That the offspring tend to inherit the peculiarities of their parents.

"3. That of those which come into existence, only a small number reach maturity.

"4. That those which are, on the whole, best adapted to the circumstances in which they are placed are most likely to leave descendants."

Darwin commenced his work by discussing the causes and extent of variability in animals, and the origin of domestic varieties; he showed the impossibility of distinguishing between varieties and species, and pointed out the wide differences which man has produced in some cases—as, for instance, in our domestic pigeons, all unquestionably descended from a common stock. He dwelt on the struggle for existence (which has since become a household word), and which, inevitably resulting in the survival of the fittest, tends gradually to adapt any race of animals to the conditions in which it occurs. While thus, however, showing the great importance of natural selection, he attributed to it no exclusive influence, but fully admitted that other causes—the use and disuse of organs, sexual selection, etc.—had to be taken into consideration.—*Sir John Lubbock, in Popular Science Monthly.*

CURIOUS ACOUSTIC PHENOMENON.—M. Reulaux reports a singular instance of the production of sound by natural causes. During a hunt upon the Roderhacherthal he passed through a valley, broad upon the eastern side, but narrowing rapidly towards the west, so as to form a kind of defile. The wind was blowing from the southwest, and the observer was marching upon the eastern declivity, when he seemed to hear repeated strokes of a fine deep-toned bell. There was no bell in the neighborhood, and other sounds which he heard soon proved that the phenomenon was meteorological. The sounds increased in intensity, and then diminished after having passed through a maximum. They resembled, at times, those of an organ, and at other times those of a harp or violin. At the entrance of the defile, from which the sounds seemed to come, there arose a strange agitation of the air, when the sounds became confused, and some of the notes suddenly ceased. M. Relaux supposes that currents of air were forced through the gorges, and that the sound was due to a conflict between the exterior and interior air, which produced musical vibrations. There was a very marked difference of temperature between the upper and lower portions of the valley, so that the upper and cold current pressed upon the lower and warmer air, thus closing the gorge so as to make a kind of tube. There appeared to be no wind, except in the lower part of the gorge.—*Les Mondes.*

PERIODIC VARIATIONS OF GLACIERS.—M. F. A. Forel, of Morges, presented to the first general meeting of the Swiss Society of Natural Science his investigations upon the periodic variations of glaciers. The present remarkable period of glacial retreat began about 1840 in some places, but the Unteraar glacier did not begin to diminish until about 1871. The period is now coming to an end and many of the glaciers are beginning to increase again. The differences of length are immediately traceable to periodic variations in the velocity of flow, which are due to corresponding variations in the thickness of the glacier. These are due partly to differences of snow-fall upon the summits, partly to variations in the summer heat; the latter cause has probably only secondary influence. The retreat which is just ending is attributable to a deficit of snow which dates back from 40 to 60 years and a series of warm summers for the past 20 years.—*Les Mondes.*

FATAL ACCIDENT AT POWDER WORKS.—An accident, most fatal in its results, occurred at the Black Powder works, owned by the Vulcan Powder Co., at Stege Station, Contra Costa County, Monday last. Six white men and six Chinamen were burned to death and two or three badly injnred. The fire originated in the incorporating house, and almost instantly spread to the dry house, some 100 feet distant, hut connected hy an elovator. The men attempted to escape, hut the fire caught them all. These works are between the late Enreka Powder works, which exploded in March, 1881, and the Tonite Powder works. These latter works were not injured in any way hy either the explosion or the recent fire.

AT a meeting of the new managers of Ingersoll Con., the following Directors were elected: Jo. Clark, President; J. B. Lewis, Vice-President; W. B. Carr, L. C. McAfee, S. Steiner, J. C. Stump, E. M. Heller; Calvert Meade, Secretary.

The Mining Share Market.

Stocks continue dull. There is not a single mine on the Comstock that is in two figures with respect to price as expressed in dollars. The highest priced stock is the Union Consolidated, which is now selling at $9.62½, or less than $1,000,000 for the mine, which, a few years ago was paid for 5,000 shares of the stock. At that time the mine was supposed to he worth $20,000,000. Comparatively good Comstock mines can now he hought for $100,000. Others can he hought for $50,000, and at least one for $5,000, or at that rate. As to the honanza in Noonday mines, the Bodie *Free Press* says:

It may he stated that the development is in a joint winze between the Noonday and North Noonday mines, which has attained a depth of 200 ft. on the vein helow the 512-ft. level. Some rich ore was encountered in sinking this winze, in a short drift about 70 ft. from the hottom. This ore has continued to improve in quantity and qnality. Fourteen ft. from the hottom a drift was run north 40 ft. and south 15 ft., on the foot-wall of the ledge, throughout which there is about four ft. of rich ore, the halance of the vein, so far as opened, being about the same quality as in the levels above. At the lowest extremity of the winze a crosscut has heen run in 20 ft., hut as yet the hanging wall has not been encountered. Six ft. of this ore on the foot-wall, or western side of the vein, is rich, as is also some in the eastern face of the cross-cut. The ore is of a different character in many respects from any which has been found in the district, which is not surprising, considering that it is found at a greater depth helow the water line than at any other point in the camp. The metal is principally in the shape of gold and silver sulphnrets, and the assays turn out much hetter than one accustomed to the general rnn of Bodie ores would snppose from looking at them. The rock is said by those who are familiar with the subject to resemble in appearance the ore from the old Con. Virginia and California honanzas.

The *Bulletin*, in speaking of the Yellow Jacket mine, says:

The Yellow Jacket mine is one of the very few mines in Nevada, operated in California, that is incorporated under the laws of Nevada. That, however, is not the only peculiarity of the mine. It is also one of the oldest claims on the Comstock, and has at times heen the most popular and speculative. Not to hold Yellow Jacket was once considered equivalent to heing out of stocks altogether. The mine has not heen so prolific as Belcher and Crown Point, hnt up to the time of the opening of the last honanza in those mines, it was the leading claim in the Gold Hill group. Its hullion output is reported at $14,372,000. There have heen 25 dividends paid, amounting to $2,184,000, hut all these were paid prior to the last discovery of ore in the Crown Point and Belcher mines. The report for June 30, 1867, shows five dividends of $600,000 in that fiscal year. The last dividend paid was August 5, 1871. Since then things have not heen very prosperous at the Yellow Jacket mine. Had the claim heen abandoned at that time, it would have heen of immense advantage to stockholders. But for the ore discovery in Crown Point, about that time, it is thonght that the whole Gold Hill group would have heen forsakeu or passed to the control of foreign capital. Since 1871 the mine has heen a constant sonrce of expense. The stock was originally divided into 24,000 shares. But the great demand for money necessitated an increase in the numher of shares to 120,000. The forty-fonrth assessment is now in process of collection. This will make a total of $5,358,000 drawn from the pockets of stockholders, against $2,184,000 received in dividends. Of the assessments, 14 have heen collected in a little over three years, the same aggregating $1,560,000.

Bullion Shipments.

We quote shipments since our last, and shall he pleased to receive further reports:

Silver King, 22d, $14,425; Eureka Con., 6th, $20,289; Standard, 14th, $20,210; Star, $2,149; Northern Belle, 20th, $6,561; Mount Diablo, 21st, $7,706; Christy, 22d, $2,205; Contention, 25th, $15,285; Eureka Con., 21st, $10,801; Standard, 21st, $17,869; Gold Hill, 12th, $28,000; Northern Belle, 23d, $7,056; Lyon Mill, 20th, $16,850; Tip Top. 20th, $10,398; Monnt Diablo, 25th, $9,082; Christy, 24th, $2,230; Bodie, 21st. $7,772; Star, 24th, $2,280; Contention, 25th, $17,764 11; Enreka Consolidated, 22d, 23d, 24th, 25th, $22,492 11; Bodie Tunnel, 29th, $3,100; Germania, 21st, $5,000; Hananer, 21st, $2,400; Horn Silver, 21st, $1,000; Barhee & Walker, 21st, $1,978; Roht. E. Lee, for February, $60,000; Horn Silver. 22d, $12,500; Germania, 23d, $1,840; Hanauer, 23, $2,700; Mammoth, 23d, $2,428; Horn Silver, 24th, $10,000; Frisco, 24th, $5,449; Mammoth, 24th, $1,349; Horn Silver, 25th, $10,000; Barhee & Walker, 25th, $1,592.

ARIZONA HYDRAULICS.—The Prescott *Courier* says: Messrs. Harrington and Smith, from the hydraulic mines of lower Lynx creek, were here yesterday. Eleven men are now employed in the diggiugs; two strings of sluices are run. The gravel gives, hy pan process, from one-half cent to two cents per pan. No clean-up has, as yet, heen made. Ahout 175 inches of water are nsed, 75 for the pipes and 100 in the ground sluices. These diggings are not to exceed eight miles east of Prescott. They are extensive and though not as rich as diggings we have seen, are rich enough to pay well when properly worked, as they are hy those who are now working them. We know of a great many other good deposits of gravel in this county which, in a year like this when water is ahundant, should not he permitted to retain the gold that is in them.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

VOLCANO.—Cor. Amador *Ledger*, March 25:—The storm has increased the supply of water to an extent unknown before this season, enabling miners to crosscute work on a larger scale. The Tunnel company are able to run almost continually, thereby rapidly enlarging the vacuum in the basin. If the supply continues for two months the clean-up will send the stock up booming. The Golden Gate has shut down for a short time, for the purpose of making some necessary repairs. The mill at the Acme has been started up.

HAZARD.—The Hazard claim, near the Bunker Hill, and owned by A. Hayward, is employing a force of 6 men under the superintendency of H. Rees.

MARYLAND.—No developments worth speaking of have been made at the Maryland claim. The English company have been prospecting for 3 years, spending a large amount of money. Previous to their operations at the Maryland, the same company had expended in the neighborhood of $2,000,000 in the purchase and development of the Original Amador, at Amador City, without reaping any benefit commensurate with this vast outlay. It is hoped that this wealthy and enterprising company may yet succeed in striking a permanent and paying mine in the county where it has spent so much in the search therefor.

KELLY G. M. CO.—The Kelly Gold Mining Co. is comprised mainly of Boston capitalists, although incorporated in the State of Maine. The mining ground which it proposes to develop consists of 3,000 linear feet on the main mineral belt which runs through Murphy's ridge, about 2½ miles south of Jackson. Ore can be broken at five different points in the tunnel, and from the shaft, and run to the mill at trifling cost. There is no question about the quantity of rock being there to keep the 20-stamp mill running steadily. The one point that remains to be determined is whether the rock contains gold in paying quantities. If it surrenders $5 per ton it will pay. All of it, we are informed, prospects well; but no test by mill process has been had; and until the batteries have spoken on this vital question, all conjectures are vain. The 20 stamp mill is rapidly approaching completion. A little track laying and some work on the reservoir is about all that remains to put the mill in running order. It is a substantial piece of work. The stamps are 750 lbs. each. Water will be the motive power, supplied from Horne's ditch. It has a pressure of 250 ft, and 40 inches will be sufficient to run the machinery. It is thought that from 40 to 50 tons can be put through daily. Altogether, there is an air of thrift and good management about everything connected with the works. Blacksmith shop, lodging house, and everything complete, but not the least approach to extravagance. About 30 men are employed steadily, and they are paid regularly every month. Should this mine turn out well, there will be no lack of Eastern capital to take hold of other dormant claims in that mineral section.

BUTTE.

OCON MINING PROPERTY.—Oroville *Mercury*, March 24: Situated 32 miles from Oroville, on the Quincy stage road, near the line of Butte and Plumas counties, and not far from Walker's plains is the Black Rock hydraulic mining claim of 110 acres, which is held under a U. S. patent by Lewis Burwell, W. Dana Perkins and Moses M. Drew. Connected with the property is a ditch with a capacity of 1,500 inches, which takes the water from Grizzly creek, supplying a sufficient quantity to run the mine for 3 months of the year only. A continuation of the ditch is contemplated to tap Buck's creek, which, with the aid of reservoirs, will afford a constant supply for the entire year. In 1868, the Black Rock mine was slightly worked, the hydraulic apparatus being 7-inch iron pipe, to which was attached canvas hose and an ordinary sheet-iron butt with small brass nozzles The depth of gravel is from 80 to 200 ft, and prospects are obtained in each pan washed from the extreme surface to bedrock. About 20 days' run at that time yielded $12,000. The death of one of the owners of the Black Rock about that time and the delay in settling his estate caused a removal of the iron pipe and apparatus for working the mine, and it has never been refitted. The gravel was reached through a tunnel about 400 ft long, and dumped into Marble creek, the distance from the mouth of the tunnel to the bed of the canyon being considerable and having a fall of fully 1,000 ft. The tunnel at the upper end is 40 ft in the bedrock below the bottom of the gravel channel, and is thought to be low enough to work out the entire claim. The blue gravel—some 20 ft in depth—it is said will pay 10 cents to the pan, which is remarkable, if our informant be not mistaken. Several dry ravines, and capacious, are contiguous to the dump that can be cheaply dammed for the impoundage of tailings, guaranteeing the certainty of working even should the opponents of hydraulic mining succeed in closing down those mines which dump directly into the flowing streams. It is the intention of the owners to begin operations during the summer upon an extensive scale. . . . John J. Meredith is said to be taking out considerable gold at his mine on Butte creek, near American ravine. He is ground sluicing where there is abundance of abraded quartz. . . . About the 15th inst., the Scott's Bar company, L. M. Russell, Supt., began hydraulicing upon their mine on Butte creek just above the forks. . . . On Riley's ravine, between Lovelock's and the junction, I. N. Smith, A. Corbin, Jo. and E. Bowers, J. Suffrain, Doc. Watkins and Mr. Russell are all working with varying success. . . . The Bumble Bee ledge, in Yellow Jacket ravine, near Lovelock's, is the most waspish location we have heard of lately. It is owned by John Matlock, John Boll, Jacob Harvey, Fred Long, John Benner and I. W. Kitchen, who propose to unearth some rich rock from it as soon as the snow will admit of work upon the claim.

CALAVERAS.

GLENCOE.—Cor. Calaveras *Chronicle*, March 25: Since my last the Valentine people have done hut very little, their mill being full of ore for crushing. As soon as the necessary power can be obtained they will be set running again. The ditch (Clark's) which furnishes the motive, having been closed by snow and ice during the winter. I hear it will be in order and running within the next ten days.

THE NORWICH has been pushed ahead constantly during the winter, and continues to improve in the quality and quantity of ore raised. Do not be surprised if you hear of a "bonanza" in old Calaveras in the very near future.

THE FIDELITY.—The Fidelity has changed its management in part, Mr. J. L. Hoey having resigned the assistant superintendency; the work is now being pushed under Mr. J. A. Steel's charge. The shaft is being sunk as fast as possible, though the flow of water has been quite strong. The ledge is proving one of great value—the deeper they go the larger the lead and the better the ore. I understand this company are preparing to build a 10-stamp mill on the property during the coming summer.

LEWIS & FAIRCHILD.—This mine continues to produce excellent milling ore. Its proprietors are very energetic, and are making good progress in its development.

THE SAN PEDRO.—This property has heretofore produced largely of gold bearing rock. It has a small steam engine and hoisting works, and is being put in condition under the management of Mr. Dewey, a former resident of Placer county. Work has also been resumed on the old Frank Barney mine. This mine has yielded in the past some very rich ore. It is under the superintendency of Mr. T. J. Severce, who is having the tunnel placed in first-rate condition. It is being whispered around town that the owners of the Banner mine are taking the necessary steps to obtain a U. S. patent to their property, preparatory to their again sinking upon the mine, and the

introduction of a new and more powerful pumping engine and pump. There seems to be a general determination to "put the best foot forward" in this section during the coming spring and summer.

EL DORADO.

SPANISH DRY DIGGINGS.—Cor. Georgetown *Gazette*, March 24: This being essentially an old mining camp, some few items regarding the most promising and prominent mines may be of interest to your readers as well as letting the outside world know some of the work we are doing. The McCrubb claim, worked by Gilbert & Davis, continues to keep up its reputation, is working steadily and pays well. The Hines & Co. claim is now being placed in splendid working order by its untiring and energetic manager. This, as well as the McCrubb claim, is located on the famous Cedarburg belt, and the outlook for the coming season is most prosperous. The Davis claim, also located on the Cedarburg belt, has probably had more continuous work done on it the past year than many others in this district. All its appointments are new and first-class; the hydraulic pipe used, being extra heavy and with a pressure of about 250 ft, is doing very fine work. A large cut has been run on this claim during the past year, to prepare the way for systematic working, and on a scale not before attempted. A long string of sluices are now being placed in position, and the work of opening the many seams containing gold, and which the large cut has in part developed, will begin as soon as all is prepared. This is a fine property, and the owners rightly feel a little jubilant over the prospects for the coming season. At the Cherokee Flat, worked by Freuchtricht & Co., their 7-stamp mill is running steadily with good results. The Spanish Dry Diggings claim, worked by Sornberger & Withington, has been put in good working order, and is expected to take out pay by the end of next week. The old Orit claim is now worked by the Murray Bros. with a good show to strike one of its famed rich pockets ere long. Walker, Pile & Co. are and have been steadily working their ground on Summit hill, and are now drifting on seams 150 ft below the surface. Their ground has paid them steadily for the past three years. There are quite a number of other mines here now at work, but fearing this communication is already too long, I will reserve notice of them to some future time; enough has been said, however, to show that there is considerable life and pluck left yet in this old mining camp.

THE rich strike made in the Rich Gulch seam mine, two miles below this place, turns out to be 205 ozs, or nearly $4,000. The mine belongs to Messrs. Armstrong & Baldwin. Mr. Armstrong had leased his half of the mine to Mr. Adams for 30% of what he might take out. Adams' time expires May 1st. We reckon he will make the best use of his time.

FRESNO.

OERTRUDE.—Cor. Mariposa *Herald*, March 25: The Surprise mine, owned by the McDonald Bros., is being steadily developed by them. They are down about 125 ft, with a fine body of milling ore in sight. The Red Rover, owned by Messrs. Silsmuer, Baker, Crooks and Cox, is being steadily developed by them. They are down over 40 ft, and have a fine 2½-ft ledge of very rich quartz, and as they go down it increases in richness, and I think in a short time it will be one of our best paying mines. The Antelope, the extension of the Red Rover, is being developed by its owners, Peterson & Oxindine. They are down over 70 ft in their shaft, and have a fine ledge of good milling ore. The King's gulch mine, owned by Jim Hamilton and others, is being steadily developed by them. They are down 35 ft, and have a 7 ft ledge of first-class ore. This is, without doubt, one of the best prospects in that section.

INYO.

DARWIN.—*Inyo Independent*, March 25: The Defiance furnace closed last Thursday. In last short run of 11 days 1,000 bars of bullion were smelted out.

DEEP SPRINGS.—A reliable report comes from Deep Springs this week. The Half Dollar mine is assuming a very favorable appearance. They are down in the lode about 90 ft and find good ore in the bottom, assaying from $140 to $227. A crosscut has been commenced and still more favorable results are expected as soon as the foot wall is struck.

MARIPOSA.

DILTZ MINE, WORK RESUMED.—*Gazette*, March 25: From Mr. Abel Mann, an employe upon the works, we learn that since Cap. Diltz' return home from the East, work at the mine has been resumed with the usual vigor given to it, aided by the abundant rain recently fallen, which affords sufficient water to supply the several ditches appendant to the mine. Cap. Diltz has opened the flood gates of his reservoirs, and it at present washing away the large bank of pay dirt which lies against the mine on the north side; and by artificial means of sluices and quicksilver is catching up the deposits of free gold which the earth at the mine and vicinity is known to contain in quantities to justify the outlay whenever a sufficient head of water can be obtained. During the period of removing the earth and obtaining gold therefrom, a double purpose is served. Large quantities of float gold bearing quartz is exposed, which are gathered up and piled for milling purposes. Our informant says free gold is frequently to be seen in the rock, as it is undergoing the process of water and being piled up.

COULTERVILLE.—Mr. Hunt, superintendent of the Compromise mine, came down yesterday with a small ball of retorted gold, about the size of a man's head. This mine is said to be constantly improving. The Martin & Walling is shut down, the pumps taken out of the shafte, all hands discharged and the work stopped. The mine has not been condemned as yet, for I understand they intend running a tunnel from Gentry's gulch. This tunnel will be of greater length than the Banderita tunnel. It will be a mammoth undertaking, but they are men of means and grit and nothing will deter them. Mr. Mast has taken a small force of men and commenced work on the Bower Cave mine. Mr. Douglass is still prosecuting work on the different mines of his company.

ENTERPRISE.—*Herald*, March 25: I learn that the Enterprise Co. has at last succeeded in striking its vein ore at a depth of about 400 ft. The tap was made by a tunnel, which has cost a large amount of outlay, money and labor both. The vein is about 3 ft thick, very hard, and tightly froze to each wall, which is also very hard. The prospects are fair for milling rock. The rock bears pretty much the same character it did 100 ft below the surface.

MONO.

BODIE NOTES.—A *Free Press*, March 22: *Free Press* reporter, in company with Martin Jones, visited the recent development in the 500 level of the Standard Con., on Wednesday. It is a big strong vein, from 5 to 7 ft wide, of very rich ore. It has been intersected by two crosscuts, 200 or 300 ft apart, and a drift is being run on the vein between them. The crosscut further south is about 200 ft north of the Bodie line. There is an upraise of 50 ft on the vein, and a drift north and south from the upraise. It shows rich ore everywhere, and the entire vein will mill up in the hundreds. The "suspicion" of the New York Mining Record that this ledge is the property of the Bulwer is quite without foundation. A much more reasonable suspicion is that it is the northern extension of the old Bruce vein of the Bodie, though found at a greater depth than at any other point.

NEVADA.

THE NEW MILL STARTED.—*Transcript*, March 25: The new mill of the Merrifield Co. started up Saturday with 10 stamps. It works to perfection. The timbers are already to put in for 10 more stamps in a few weeks, giving the mine 40 in all. Geo. Allan, of the Nevada foundry, is the gentleman who had the contract, and a good job has he done.

HEAVY FLOW OF WATER.—The water is coming into the workings of the Eureka No. 2 mine so rapidly that all the available power is required for pumping purposes. Hoisting of ore is interfered with temporarily as a result, but will be resumed as soon as there is less pumping to do. The ledge shows well in gold and another crushing will be made at an early day.

CHAPMAN'S RANCH.—Joseph Lawrence, John McLaren and several others who leased the Underwood & Murphy claim for a year, have about 250 tons of good ore on the dump. Six or seven men are at work in the mine. The Virginia City Co. have 180 tons on their dump, and are taking out more as fast as a force of eight men can do it. The ledge is a very large one. John Curry got $500 worth of specimens out of his mine last week. He is also extracting a liberal quantity of average ore. Mr. Green has bonded his claim to a San Francisco company that talks of erecting water-power hoisting works thereon. Mr. Cohen and Mr. Leahy will soon begin to work on their respective locations and continue it through the summer. It is likely that a mill will be erected in the vicinity of the above mines if they continue to show signs of permanency when more thoroughly developed. Judging from present indications it is going to make one of the best producing locations in the district.

STRUCK GRAVEL.—*Transcript*, 21: Work on the Shurtleff drift claim at Alta hill was resumed January 1st, and has ever since been pushed vigorously. The main tunnel is 800 ft to an upraise of 20 ft, beyond which it extends 450 ft further where a promising deposit of gravel has been encountered. The dirt prospects well. It is being taken out for a distance of 14 inches above bedrock, and a clean-up will be made as soon as there is a good supply on the dump.

WILL SOON CRUSH.—*Foothill Tidings*, 25: Underground work is going steadily on at the Ford & Mullen mine and good milling ore, as well as rich specimen rock, is constantly being hoisted to the surface. About 25 loads of rock now on the dump will be hauled to the custom mill and crushed as soon as the roads get in a passable condition. A few boxes of very rich specimens were deposited in Judd's vault lately.

THE ALPHA MINE CONTEST.—A contest is going on at present in the Superior Court between attachment creditors of the Alpha mine and a number of persons having mechanics' liens on that property. The law prefers the liens of laborers or material men to those of all persons who attach or incumber the realty after the labor is begun or material furnished. Hence this contest.

EAST EUREKA MINE.—Several of our monteyed men have interested themselves in the East Eureka (O'Connor) mine and the company will organize on Wednesday next.

PLACER.

NOTES.—Placer *Herald*, March 25: The tunnel in the Conrad mine is being extended to strike the pay chute that was struck in the main shaft. Wm. Hooper is working a ledge near Mrs. Kittler's hotel at Empire. It is supposed to be an extension of the old St. Lawrence. He has a strong vein, and his ore thus far has paid about $20 per ton. He is at present running a tunnel to drain the surface water. At the Crater mine some 12 or 15 men are at work steadily. At present they are sinking from the 700 to the 800-level. The Tremelling Bros.' mine, on Believue hill, continues to pay well. The last crushing, it is reported, went about $60 per ton. James Butts has opened up the old Hathaway lead, a short distance below Ophir. About a month ago he completed a 5-stamp steam mill, since which time he has been crushing steadily. The ore, though not of a high grade, is uniform and the ledge is quite large, being from 3 to 4 ft thick. In the opinion of some this will soon be the boss mine of Opbir district. New pumping, hoisting and crushing works are being erected on a mine near the old Eclipse. The Julian continues to run steadily, which is the best evidence of its prosperity.

THE IRON MINE.—Nevada *Transcript*, March 21: County Surveyor Hartwell returned a couple of days since from a professional trip to the vicinity of the iron mine at Hotaling, in Placer county, which is in an air line about 25 miles south of this city and less than 3 miles on the other side of Bear river which forms our county line in that direction. Three of the iron company's charcoal camps are on this side of the river and the fourth on the other. At each of these camps are 6 kilns having a capacity of 60 corde of wood apiece. They are all "charged" now, and will soon be burning. A large force of men are employed chopping more wood. At the mine masons are at work relining the furnace with fire brick, which will take 2 or 3 weeks; while a new shaft is being put down in a hitherto unprospected place with the best of results. A ledge of richer ore than ever before developed by the company has been found. As soon as the weather settles and the roads become passable the mine will be started up again in all departments and worked more extensively than ever before. It is impossible to transport the wood and charcoal as the roads are at present. Land in that section has doubled, and in some instances trebled in market value since the iron mine was started, on account of the demand for wood that has been created. The timber is mostly small oak, worth 50 cents a cord as it stands. The average yield per acre is 20 cords, and the ground when cleared is excellent for agricultural purposes. Most of the large trees, especially the pines, have fallen before the onslaught of the sawyers who some years ago paid their respect to that country.

SIERRA.

ITEMS.—Sierra *Tribune*, March 25: The snow is 7 ft deep in our streets, the deepest it has been for seven years. The last clean-up made by the Bald Mountain Extension company amounted to $1,200. The Bald Mountain company found it necessary to discharge some of their men last week, owing to the limited amount of timber on hand. Alleghany has been rather quiet this winter, but spring promises to bring livelier times to our neighbors. It is confidently expected that a number of new mining enterprises will be inaugurated in that vicinity next season. Will Hanly, who has had the Golden Star drift mine leased for the past year, is working his usual force in taking out pay gravel. The main tunnel has been run ahead some distance under his supervision, but no attempt has been made as yet to open out new ground.

BALD MOUNTAIN EXTENSION.—The Extension company encountered in the main tunnel last week what is supposed to be a slide or horse of lava. They then started a raise at a distance of about 40 ft ahead of the former one, and near the face of the tunnel, and in 15 ft struck fine looking gravel. This being 6 ft nearer than when tapped before, shows that the bedrock is pitching ahead of their main tunnel, and will be reached in a little distance further ahead if the present indications hold good.

THE SUFFOLK mining company at Wahoo has completed its dump yard, and will commence building as soon as possible. The mine continues to pay well. The main tunnel is still being pushed ahead.

TUOLUMNE.

PROSPECTS.—*Union Democrat*, March 25: Mining and agricultural prospects were never better in this county at this period of the year than now. An abundance of rain has fallen, the mountains are deeply covered with snow, which assures a good supply of water until late in the season. The past few days have been warm and genial, which if continuing will soon cover the hills and valleys with luxurious foliage. The great needful to put life into these hills is water, with it there is no telling what may not be accomplished. It is here forming a good basis for a prosperous season.

RUNNING.—*Independent*, March 25: Several mines have commenced running again since the severe cold weather has left us.

NEVADA.

WASHOE DISTRICT.

UNION CONSOLIDATED.—*Enterprise*, March 25: On the 2700-level, east crosscut No. 1 has been extended 27 ft, and north No. 3 12 ft. The joint Sierra Nevada east winze has been sunk and timbered 10 ft. On the 2500-level ore stoping out ore. The amount of ore extracted during the week from the 2500 and 2700 levels was 293 tons and 800 pounds.

OPHIR.—On the 2700-level the main south lateral drift has been connected with the joint California east crosscut. During the week 22 tons and 400 pounds of ore have been extracted from the croppings, and 70 tons and 1,560 pounds sent to the mills.

CONSOLIDATED VIRGINIA.—On the 2700-level the joint C. and C. east drift drill hole has been extended 80 ft.

CALIFORNIA.—On the 2700-level the joint C. and C. east drill hole has been extended 80 ft.

MEXICAN.—On the 2700-level the main north lateral drift has been extended 24 ft. The upraise from the main south lateral drift was extended 22 ft, the face showing fair milling ore. During the week 112 tons and 1,000 pounds of ore were extracted.

SIERRA NEVADA.—The winze in east crosscut No. 2 on the 2500-level has been sunk and timbered 11 ft; north drift No. 2 has been advanced 26 ft, and the main north lateral drift 32 ft.

YELLOW JACKET.—The pumps have been kept running at five strokes per minute since the last weekly report, as per agreement with the Bullion. The water in the mine this morning is 207 feet above the 2300-level station. During the first part of the week it rose very slow, as it was then filling the 2000-level (old works), which extends through the Crown Point, Belcher and Imperial mines. The past 24 hours the water rose 5 ft 0 inches.

ALTA.—The diamond drill is running in the west drift as a precaution against water. Rock hoisted, 460 cars; wood consumed, 37 cords; strokes made by the pump, 48,450.

BRISTOL DISTRICT.

MAYFLOWER.—Bristol *Times*, March 18: The Mayflower mine is still improving and showing up large bodies of high-grade rock. The chutes and ore houses full and enough ore in sight to keep the mill poundlug away for months.....Oilmer & Sallsbury will this week put a large working force on both the Tempest and Iron mines. Developments will be rapidly pushed ahead and every effort made to show up two of the largest bonanzas in the couutry.....The Noonday is still improving as work progresses, and the owners seem to be highly elated over the matter. This mine will in a short time become one of the standing mines of the district. It is said, that a large sum was offered for this property recently, but was refused.....The mill was shut down this week on account of a scarcity of water. The tanks are now all filled, and stamps will probably be dropped this coming week with a plentiful supply of water on hand, and everything in and about the mine and mill in the finest shape possible for a long and prosperous run.....It is now a settled fact that the Day company will start up the furnace here the 10th of April next. All the arrangements have been perfected for hauling of ore and the receiving of coal immediately. Men are already out in the woods burning, and it is expected that enough coal will be in on the 10th to keep the furnace running for 00 days. General Manager Henry Oodhue, of the Bristol S. M. Co., arrived last Monday from Minneapolis, Minn., by private conveyance. He is well pleased with what he has seen here, and particularly so indeed about the mill, where he has found everything in splendid shape and more to show for the money invested than he at first supposed.

CENTRAL DISTRICT.

ORE.—*Silver State*, March 22: One of Alex. Wise's teams arrived at the Winnemucca reduction works yesterday, with 14 tons of ore from the Keystone mine, in Central district.

COLUMBUS DISTRICT.

NORTHERN BELLE.—*True Fissure*, March 22: The work of cutting out for the new station still progresses favorably; when completed, it will be known as the fifth level. Everything is being got ready to commence running a drift to connect with the main winze on which sinking is being done from the fourth level. This winze is now down 125 ft on an incline and is very hard in the bottom, but 10 ft having been made since last report. The other shaft levels have the same appearance as last week. The levels above the adit are producing the usual quantity of ore, and the development between the seventh and eighth levels is still looking well; otherwise, the appearance of this section of the mine remains unchanged. Fifty-five tons of ore are being extracted and sent to the mills daily, both of which are running steadily. Mill No. 1 is running on Mount Diablo ore and on half the time only. Bullion shipments amounted to $13,618 74 for the week ending March 23d, and a total of $43,108.04 on March account to the same date.

MOUNT DIABLO.—The stopes above the east drift on the third level show no change. The stope below the north croscut from the west drift on the third level shows considerable improvement. The stope near the center of the mine below the second level is looking well and yielding considerable ore of very good grade. The stope above the second level of the west drift shows no change. The stope between the second and third levels on the winze from the west drift shows a larger ledge of better ore, and the prospect is good for the ore to open. The stope east of the shaft, first level, shows a narrower ledge than at the last report, but continues to yield first-class ore. The stopes west of the shaft on the first level continue to yield considerable $65 ore. Bullion was shipped as follows: March 18th, $7,048 47; March 21st, $6,766.53

EAST MOUNT DIABLO.—The work of crosscutting from the main east drift has commenced, and some good developments may be looked for at an early day.

GENERAL JACKSON.—The extraction of ore in this mine still continues, the stopes yielding fairly. The ore coming out is very clean, and of high grade.

EUREKA DISTRICT.

BULLION.—*Sentinel*, March 24: During the first half of the present month the Eureka Con. company shipped $67,027.25 in bullion. Fifty additional miners have been put to work in the Richmond mine during the past three weeks, nearly all of whom are $4-a-day men. Two loads of ore were shipped yesterday from the Eureka tunnel to the Eureka Con. works. Regular daily shipments will be made. We are informed that the Richmond company intends refining over a large amount of the lead bars they have on hand, as there is a sufficient quantity of silver remaining in them to pay a profit for working. It was reported on the street yesterday that the Richmond company intend shutting down the furnaces. We were unable to learn the cause for doing so, and came to the conclusion that there was no foundation for the rumor.

FAIRVIEW DISTRICT.

LEAD ORE.—Bristol *Times*, March 18: Bob Wilson and Andy Hear have 2 ft of heavy lead ore, assaying high in silver, in their claim in Fairview district, between 3 and 4 miles from here.

HIGHLAND DISTRICT.

RICH.—Pioche *Record*, March 18: Several very rich and handsome specimens have been brought into Pioche from the Last Chance mine of Highland district.

PIOCHE DISTRICT.

ANALYSIS OF RAYMOND & ELY BLACK ORE.—Pioche *Record*, March 18: Last July, 2,020 lbs of the Raymond & Ely black ore was shipped to the Frisco mining and smelting company of Frisco, Utah, to be analyzed and worked, and following is the result: The 2,020 lbs of ore went 24 8 ozs in lead, $2.97 ozs silver, 0.335 ozs gold. After this ore had been concentrated, there was 970 lbs, showing 48 3 ozs lead, 85.45 ozs silver, 0.452 ozs gold. The waste went 3.0 ozs lead, 64 88 ozs in silver, 0 291 ozs gold. Analysis: Lead, 16.60%; silver, 0 34%; zinc, 20 54%; iron, 3.52%; sulphur, 23.41%; aluminum, 7%; lime, a trace; silica, 20.00%.

ARIZONA.

SANTA CATARINA.—*Star*, March 21: A rich vein of high grade red oxides of copper has been struck in the tunnel on the Apache mine. The indications are the best for reaching a large body of ore soon in the tunnel. Also fine green carbonates are showing up in the shaft at 80 ft deep that average 22% copper. Every foot sunk on the mine shows the most encouraging results, and demonstrates this to be one among the most promising copper properties of southern Arizona. The machinery is being rapidly placed in position. The sawmill will soon be ready for operation to cut out lumber for timbers for the smelter, and the company is a strong one, and is sparing no pains nor expense to place their mines on a producing basis. They have every show for a rich bullion product to speedily repay them for their outlay.

IDAHO.

GALENA.—Wood River *Miner*, March 18: Two ft of solid galena ore was struck in the Jay Gould mine yesterday, which will run above 200 ounces in silver to the ton.

ITEMS.—Mr. Bunting, of the Northwestern Forwarding Co., Blackfoot, was in town this week, looking up the forwarding business. W. Thompson, foreman of the Little Wood River M. and S. Co.'s property, came in from Muldoon on Tuesday, and reports the new bridge over Little Wood river completed. It is 144 ft in length, 16 ft wide, 10 ft above low-water mark, and rests on four substantial piers. There are three other bridges yet to build on the new road to Muldoon. The gang of men who have been constructing the bridge are now at Muldoon, getting things in readiness preparatory to start up work as soon as the weather permits.

THE CHARLES DICKENS.—Yankee Fork *Herald*, March 25: The south vein of the Charles Dickens is improving as work progresses. Large quantities of nuggets of pure metal are being taken out. Some of these are large chunks, and very beautiful, and are about three-fourths silver and one-fourth gold. The quartz of the entire vein (nearly 2 ft) is of wonderful richness. Such a sight of mineral has never before been witnessed in even the Yankee Fork country. The ore is literally crammed with metal of every imaginable shape. The face of the drift where the ledge is so rich is about 300 ft from the surface. To-day the Charles Dickens makes the best showing, probably, of any vein of like size in the country, and if it continues much further in its present richness it will make the mine worth many millions. The rich streak has been followed a distance of 200 ft, and is getting better and stronger all the time. If any camp in the United States can beat Yankee Fork for rich and plentiful ores, we would like to hear of it.

MONTANA.

ORE.—*Inter-Mountain*, March 20: The ore now being extracted from the Morning Star is improving in quality, the assays to-day being $58, $99 and $128 per ton. Eight tons per day is now the regular output. The St. Lawrence has recently shipped 14 tons of 50% copper ore, and has 75 tons of first and second-class ore on the dump. The mine is developing into a valuable property. Two hundred tons of copper are on the dump of the Modoc Extension, and the owners of the property are making frequent shipments. Placer mining in the vicinity of Butte will soon recommence. Operations on the Salvage have been temporarily suspended. The Bell mine shipped 00 tons of ore to the smelter yesterday. McDermott & Co. are opening up a valuable property in the Liquidator. The development of the Shonbar is already returning a handsome profit. Energetic work continues in the new three-compartment shaft of the Magna Charta. The Laura mine in the Berker district has been bonded to Eastern parties for $40,000. Much dissatisfaction is expressed as to the operation of the machinery recently placed in position in the Broadway mill at Silver Star.

OREGON.

MINING NOTES.—*Sentinel*, March 18: Cowan & Gale, of Birdseye creek, picked up a $12 nugget last week, besides several smaller ones. The late warm rain has given the Sterling company an abundance of water, and gravel is being moved fast. De Selles & Co., at Waldo, are running their elevator successfully, and will make a good clean-up soon. The Waldo hydraulic company, Winer & Simpson, are piping day and night, and moving a vast quantity of dirt. This is one of the big paying claims of southern Oregon. Oin Len is running two pipes on his claim on Little Applegate in good paying ground, and one pipe on his Palmer creek claim. Fifteen Chinese began work this week on the ditch from Palmer creek to the Red hills. It will be nearly eight miles in length, and is being built by Gin Lin. The Applegate gravel company are going to put in an elevator soon, and feel confident that it will work well. Blue Gravel and English companies on Galice are crowding things with full heads of water. All the miners in the Willow Springs and Foot's creek camps are busy again. Tom Kahler, of the Fort Lane diggings, has been cleaning bedrock with good success. Chapple, of the Star gulch mine, is getting off a large amount of gravel, and has plenty of water. W. Q. Brown, of Oakland, has purchased two more copper and nickel claims near Canyonville; price not stated. The Star gulch company made a partial clean-up this week of 38 ounces. Schumpf is still working on his tunnel at Willow Springs, the ledge showing plenty of good quartz.

NEW MEXICO.

MOGOLLONS.—Cor. Socorro *Miner*, March 18: The Cooney mine is being worked, and taking out some very rich ore from the lower tunnel, and the company will likely have a smelter working their ore some time this summer. W. R. Myers, who has charge of the M. & S. gold mine in the Great Western lode, who owns one-third of the M. & S., has let a 65-ft contract for a working shaft 390 ft, and is driving work night and day, so as to develop the property as soon as possible, and then to get machinery to work the mine. It is certainly one of the richest mines that has ever been discovered in this part of the Territory, and we are proud to say that the parties who are interested, G. O. Manchester, of Topeka, Kas., H. P. Strong, of Beloit, Wis., and W. R. Myers, of the Mogollons, are men who will be of much interest to this camp, and we wish them success. Chicago parties, who have lately bought the Parker & Potter mine, expect to have their mill here within sixty days. A great deal of work is now being done all over this camp, with good results.

TURQUESA.—Cor. *New Mexican*, March 24: Our district is getting new life into it. All the miners are at work, and rich strikes of mineral are taking place every few days. Property is changing hands, and development is being pushed forward on many new claims. Mr. H. J. Chise, of Las Vegas, is in our camp, and is much pleased with the prospects of the district. He has bought the Ark and the Monarch claims, and has let contracts on them for development. This district has as high grade ore as can be found in any district in New Mexico. Work on the Bonanza No. 3 is progressing as fast as men can do it. They are working day and night, and will soon be in readiness to take out ore with their machinery. They have partly cleaned out some old workings, done by the ancients, and it shows up a strong vein of very good looking mineral. I hear they have struck a body of rich mineral in the Pacific lode; also in the Great Western. All owners of mines will soon be able to have their ores reduced. With two smelters and one concentrator will come active development in this district.

BODIE DEVELOPMENT.—An important development has been made in the joint winze between Noonday and North Noonday. The mines are 200 ft. below the 512 level. In a vein 20 ft. wide 6 ft. of ore has been cut, which will average over $100 per ton. The metal is in the shape of gold and silver sulphurets, differing essentially from the ore in the upper levels. In many respects it resembles the top of the Con. Virginia ore body. Assays from portions range from $1,000 to $2,000 per ton. Superintendents William Irwin, Martin Jones, Thomas Buckley, R. K. Colcord, H. C. Osborne, of the *Free Press*, and others, visited the mine to-day, and by all the development is regarded as very important, considering its depth and the position of the South End district.

Chinese Immigration.

Full Text of the Bill as Paesed by both Houses.

Following is the fnll text of the bill regulating Chinese immigration as it passed the House. No amendments were made in the latter body, it he ing accepted precisely as it came from the Senate. The only changee made by the Senate were in the enacting clause, extending the time of going into effect from 60 to 90 days, end the addition of sections 16 and 17, the former prohihiting the naturalizetion of Chinese, and the latter defining the words "Chinese lahorers."

WHEREAS, In the opinion of the Government of the United Statee the coming of Chinese lahorers to this country endangere the good order of certain localities within the territory thereof; therefore,

Be it enacted, etc., That from and after the expiration of 90 daye next after the passege of this act, and nntil the expiration of 20 years next after the passage of this act, the coming of Chinese laborers to the United States he, and the same is hereby euepended; and during such suspension it shall not he lawful for any Chinese lahorer to come, or, having so come after the expiration of said 90 daye, to remain within the United States.

Sec. 2. That any master of any vessel of whatever nationality, who shall on such vessel hring within the jurisdiction of the United States any Chinese lahorer from any foreign port or place, ehall he deemed guilty of a misdemeenor, and on conviction thereof sball he punished hy a fine of $500 for each and every such Chineee laborer so hronght, and may be also imprisoned for a term not exceeding one year.

Sec. 3. That the two foregoing sections sball not apply to Chinese lahorers who were in the United States on the 17th day of November, 1880, or who shall have come into the same hefore the expiration of ninety days next after the passage of this act, and who shall produce to such master hefore going on hoard such vessel, and shall prodnce to the Collector of the Port in the United States at which such vessel shall arrive, the evidence hereinafter in this act required of his heing one of the lahorere in this section mentioned; nor shall the two foregoing sections apply to the case of any master whose vessel, being hound to a port not within the United States, shall come within the jurisdiction of the United States hy reason of being in dietress or in stress of weather.

Sec. 4. That in order to tbe faithful execution of Articles I and II of the treaty between the United States and the Empire of China, ratified July 19, 1881, in case any Chinese residing in the United States on the 17th day of Novemher, 1880, or who shall have come into the seme hefore the expiration of ninety days next after the passage of this act, shall depart therefrom, they shall, before such departure, cause themselves to be duly registered at a cnstom house in the United States, and produce to the Collector of the district at which they shall seek to re-enter the United Statee the certificate of such regietration and the Consular certificate in thie act provided for.

Sec. 5. That, in order to the faithful execution of Articles I and II of the treaty hefore in this act mentioned, every Chinese, of any class or occupation whatever, who may he entitled hy said treaty and tbis act to come within the United States, except euch ae resided in the United States on the 17th day of November, 1880, or who shall have come within the United States within 90 daye next after the passage of this act, shall ohtain the permission of the Chinese government in each case, to he evidenced hy a passport issued hy eaid government, which passport ehall he in the Englieh languge, or accompanied hy a translation into English, showing such permission, witb the name of the permitted person in his proper signature, and which passport shall state the name, title, or official rank, if any, the age, hight and all phyeical peculiarities, former or present occnpation or profession, and place of residence in China of the person to whom the paeeport ie iseued, and that euch person ie entitled hy the treaty in this act mentioned to come within the United Statee. Thie paseport and the identity of the pereon named in it shall, hefore euch person goee on hoard any veeeel, to proceed to the United States, he *vised* hy the indoreement of the diplomatic repreeentative of the United States in the empire of China, or of the conenlar repreeentative of the United Statee at the port or place from which the pereon named in the passport ie ahout to depart. Such paesport ehall he *prima facie* evidence of the facte set forth therein, and ehall he produced to the Collector of Customs of the port in the dietrict in the United Statee at which the pereon named therein ehall arrive, and afterward prodnced to the proper anthoritiee of the United Statee whenever lawfully demanded.

Sec. 6. That the Secretary of the Treasury ehall forthwith cause to he prepared and kept at the custom houees of the United Statee proper hooke, in euch form ae he shall prescribe, for the registration of Chineee who ehall he entitled, under the proviеione of this act, to the privilege of cntering and reeiding in the United Statee. Entry ehall be made in euch hooke of the name of every euch Chineee, and hie proper eignature; hie place of hirth—giving town or district—date of hirth, last place of residence hefore coming to the United Statee, place of residence in the United States, if any, name and reeidencee of hie parente, if any, date and place of arrival in the United Statee, employment or bueiness, hight, and physical marks or pecnliarities by which he may be identified. Every applicant for registration shall make oath to the facte stated in his registry, which oath shall be recorded in the hook of registry. Collectore of Cnetoms and their deputies shall have power to administer and certify to all oaths under this act.

Sec. 7. That it shall he the duty of the Collector of Customs to issue to every Chinese entitled to registry, and regietered hy him, at the time of regietration, a certificate, in such form ae the Secretary of the Treasury may preecribe, setting forth all the facts contained in snch regietration, and the data of identification prescribed in Section 6 of this act, which certificate shall he signed hy the Collector of Cnstoms of the district, or bie depnty, and attested hy his seal of office, dated the day of ite issue, and upon which ehall be written the proper signature of the person registered. A minute of the issnance of such certificate and date of issue ehall be mede in the book of regietry on the margin of the regietration. The certificate so issned to a Chinese ehall be *prima facie* evidence of the facts therein stated.

Sec. 8. That any person who sball knowingly make a false etatement nnder oath in the registration of any Chinese under the provisions of this act shall he deemed guilty of perjury; and any person who shall regieter at more than one custom house in the United States, or procure more than one certificate of registration, or alter or snhstitute any name for the name written on such certificate, or forge any such certificate, or utter any forged or fraudulent certificate, or falsely personate any person named in any such certificate, shall he deemed guilty of a misdemeanor; and upon conviction of any offense mentioned in this section, the guilty person shall be fined in a sum not exceeding $1,000, and imprisoned in a penitentiary for a term not more tban five yeare.

Sec. 9. That the maeter of any vessel arriving in the United States from any foreign place hall, at the same time he delivers a manifeet of his cargo, and if there he no cargo, then at the time of making a report of the entry of the vessel pursuant to law, in addition to the other matters required to he reported, and before landing, or permitting to land, any Chinese paseengers, deliver and report to the Collector of Cnstoms of the district in which such veseel shell have arrived a sparate list of all Chinese passengers taken on board his vessel at any foreign port or place, and all such passengere on hoard the vessel at that time. Such list shall show the name of such passengers (and if accredited officere of the Chinese government traveling on the husiness of that government, with a note of such fact), and the names and other particnlars, as shown by the respective passporte and certificates, hy the master in the manner reqnired hy law in relation to the manifest of the cargo. Any refusal or neglect of the master to comply with the provisione of this section shall incur the same penalties and forfeitures as are provided for a refusal or neglect to report and deliver a manifest of the cargo.

Sec. 10. That before any Chinese passengers are landed from any such vessel, the Collector, or his deputy, shall proceed to examine such paseengers, comparing the passports and certificatee, ae the case may he, with the list and with the passengers, and no passenger shall he allowed to land in the United States from eucb vessel in violation of law.

Sec. 11. That every veesel whose master shall knowingly violate any of the provisions of this act shall he deemed forfeited to the United States, and shall be liable to eeizure and condemnation in any district of the United Statee into which such vessel may enter or in which ehe may he fonnd.

Sec. 12. That if any consular officer, on examination of the claims and identity of any Chinese proposing to depart to the United States, shall he satisfied that such person eeeks so to do in violation of this act, he shall refuse to certify to the right of such person to so depart; and every Collector of Cnstoms shall refuse to allow any Chinese to enter the United States if he shall diecover that such entry ie unlawful nnder this act.

Sec. 13. That any pereon who ehall knowingly hring into, or canee to he hronght into, or shall aid or ahet the hringing or coming into the United Statee hy land, or who shall land, or aid or ahet the landing in the United Statee frcm any veseel of any Chineee not authorized hy law to enter the United Statee, ehall be deemed guilty of a misdemeanor, and ehall, for each person so brought or aided to come into the United Statee, or eo landed, he fined in the sum of $100, and imprisoned for a term not exceeding one year.

Sec. 14. That no Chineee ehall be permitted to enter the United States hy land without producing to the proper officer of cnetome the certificate herein required of Chineee eeeking to land from a veseel; and any Chineee who ehall knowingly come into the United Statee contrary to the provieione of this act, ehall he deemed guilty of a misdemeanor, and on conviction thereof, ehall be pnnished hy a fine not exceeding $100, or hy imprieonment not exceeding one year, or hoth eaid puniehments, in the discretion of the court; and any Chineee nnlawfully entering within the United States, or who ehall have unlawfully entered the United Statee in any way, either hy land or hy water, ehall he removed therefrom hy the Collector of Custome of any collection district in which euch Chineee may he found, at the cost of the United States, under euch regulatione as the Secretary of the Treasnry may preecribe.

Sec. 15. That thie act ehall not apply to diplomatic and other officers of the Chinese government traveling upon the businese of that government, whose credentiale in the usual form shall he taken as equivalent to the passport in this act mentioned, and shall exempt them and their body and household servants from the provisione of this act as to other Chinese.

Sec. 16. That hereafter no State court or court of the United States ehall admit Chinese to citizenship, and all laws in conflict with this act are herehy repealed.

Sec. 17. The words "Chinese lahorers," wherever used in tbis act, ehall he construed to mean hoth skilled and unskilled lahorers, and Chinese employed in mining.

Ores of Lead.

Lead occurs as an occasional constituent of a very large number of the ores of other metals, hut the minerals containing this metal as an essential constituent, in sufficiently large quantity, and occnrring in sufficient abundance to constitute them ores of lead, are exceedingly limited in numher, a single ore, viz., "galena," furnishing by far the greater proportion of thie metal; while tbe plumhiferoue minerals or oree almost always contain more or less eilver, and are accordingly described as argentiferous or non-argentiferous, according as the proportion of silver is snfficient or otherwise to pay for its extraction. The minerals containing lead, and occnrring in sufficient ahundance to he classed as oree of thie metal, may he placed under two heads: First, sulphides of lead, and second, oxycompounds of lead, ae the carhonates, sulphates, phosphates, oxides, etc., of lead. Bnt, besides these two classes, there are a number of minerale which, though not of sufficient importance to rank as ores of lead, yet are more or less ahnndant, and often associated with galena, so thet they frequently come under the notice of the metallurgist, and call for a hrief description of their qualities in tnis place.

At the head of the first division of lead ores consisting of tne sulpbides of lead, occurs "galena," plnmhic snlphide, or as it is sometimes called "hlue leed," which ie hy far the most important and ahundant ore of lead, containing, when pure, 86.61% of lead, with 13.39% of sulphnr; and which is further a most important sonrce of silver, since silver, as also gold, are probably invariahle constituents of all galenas, though in some casee their quantity may he exceedingly small. Galena forme a lead-grey mineral having a streak of the eame color. It possesses a metallic lnstre, a hardness of ahout 2.5, and a fine, coarsely-granular, or fihrons fracture; and it hae been generally considered that the more finely-grannlar, or, as they are called, steely varietiee of the ore, are more highly argentiferons than the coarse, lerge-grained epecimens; and though a comparison of the galenae of a certain locality will frequently confirm this view, yet, as a general rule applicahle to the comparison of a ooarse-grained galena from one district with a steely specimen from another, the rule is douhtless erroneous. Galena occurs crystallized in the cnbic syetem, chiefly as cnhes and octahedra, and it has a very perfect cubic cleavage. The specific gravity of this ore ranges between 7.25 and 7.7. When heated hefore the hlow-pipe thie mineral decrepitetes, then fuses, and finally yields on charcoal a glohnle of metallic lead.

Galena is very widely distributed over tbe glohe, occurring in almost every country, and both in the older and more recent geological formations. Thus it forme veins in the Devonian formation "killas" of Cornwall and Devon, in the carhoniferous or mountain limestones of Cumherland, Derhyshire, Flintshire, and the North of England, which formation yields the largest proportion of the British lead ores; while in Cardiganshire, Shropshire, Montgomeryshire, the United Statee, etc., it occurs in the lower silnrian rocks. At Freiherg, again, it occure in gneiss; in the county Wicklow, in granite; while Sweden afforde this mineral in a matrix of granular limestone. In addition to these localitiee, galena aleo occnre in Scotland—in the Lead-hille of Lanarkehire,—the Iele of Man, largely in Spain, Germany, and Northern Italy, and in emaller proportione in France and Belginm; it ie aleo found in Siheria, Algeria, and Auetralia, numerone parts of North and Sonth America, etc.

Ae above etated, the pure eulphide containe 86.61% of lead; hnt galena is very often impregnated with small quantitiee of other hodies, as eilver, gold, hlende, iron-pyrites, mispickel, enlphide of antimony, fahlore, ferroue carhonate, calamine, quartz, dolomite or pearl-epar, harytes, fluor-epar, calc-spar, etc., whilet, more rarely, it aleo containe manganeee, anthracite, etc. The preeence of theee eubetances neceeearily reducee the percentage of metal in the ore, eo that the ores emelted in England contain on the average from 70% to 80% of lead; but at Freiherg ores containing only 40% of lead are emelted; while, if other metals, ae copper, eilver, or gold, are preeent in profitahle proportions, the lead in the oree ie then extracted and paid for, althongh its amonnt may not exceed 15%. The first-mentioned associates of galena, viz., silver and gold, are of conetant occurrence in it, prohably exieting ae enlphides. The gold ie moet freqnently, however, in very small proportione, while silver occurs in very varied proportione, hut rarely exceeding 1%, while an ore containing 0.25%, or ahout 82 czs. of eilver per ton, ie considered a very rich ore; and oree aesaying only ahout 0.005% of eilver, and which yield a lead containing not more than 2 ozs. silver per ton of metal, can be profitably treated hy the Pattinson process for the extraction of the silver. Besides the ahove-mentioned associates of galena, the rarer minerals containing lead, such as plumbic carbonate, chromate, phosphate, sulphate and oxide, are freqnently associated with it.

Plnmbic eulphide also occure in combination with sulphide of antimony in the minerals Jamesonite, Boulangerite, Geocronite, and with cuproue eulphide in addition it constitutes the mineral bonrnonite.

Of the second class of lead ores or oxycompounds of lead enumerated ahove, the most important and ahundant is the plumhic carhonate, cerussite, or white-lead ore, a transparent or tranelucent mineral, of a white or grayish color, with an occasional bluish tinge, possessing an adamantine or vitreoue luster, with a colorless streak, and a hardness of from 3 to 3.5. It occurs in fihrous, compact, or earthy masses, ae also in crystals of the trimetric or prismatio eystem. This ore is found in lodee, ae also in beds in limestone, usually associated with galena; and at Aix-la-Chapelle it is raised in considerahle quantity, ae also in the vicinity of Santander, in Spain. It likewise occure in Cornwall, Devon, Yorkshire, the Lead-hille of Scotland, county Wicklow, Westphalia, France, etc.

Plumhic sulphate, or Anglesite, occure as a white, gray, greenish, and sometimes bluish, translucent, or opaque mineral, having an adamantine luster, with a hardness of from 2.5 to 3. It occurs in cavities, also in lodes crystallized in the trimetric or prismatic syetem, and ie often associated with galena and plumhic carhonate, at Anglesey, in Scotland, Cumherland, Derhyehire, Hartz, Spain, Germany, France and the United States. This compound, combined with cuprons carhonate, etc., constitntes Caledonite, and a similar mineral is known as Lanarkite.

Pyromorphite or plumhic pbosphate varies in color hetween green, yellow and hrown, and hes a white or yellowieh streak. It nsually contains plumhic chloride as well as phosphate, and certain varieties contain also plumhic arseniate. In Derhyshire, thie mineral is known as "linnets" from its peculiar color. The mineral also occurs in the Lead-hills of Scotland, in Cumberland, Durham, Yorkehire, Cornwall, Wicklow, Bohemia, Sexony, Hartz, France, the United States, etc.

Mimetesite or plumhic arseniate ie an analogous mineral to the leet, hut containe arsenio acid, in lieu of phosphoric acid, as an essential constituent. It forme a pale yellow or brown mineral, with a white streak, occurring at Redruth and other mines of Cornwall; elso in Devonshire, Cumhsrland, Saxony, France, Sweden, South America, etc.

The ores of lead found near the surface often helong to the second clase or oxycompounds of lead, and are a result of the decomposition and oxidation of galena.

Besides these sulphur and oxidized ores of lead, nnmerous minerals containing lead in large proportion occur, hut not in sufficient abundance to constitute them ores of lead; of such are plumbic chloride, mendipite, plumhic chromate, etc.

A Southern California Mining Sale.

During the pest eight days one of the most important salee of mining propsrty ever effected in eontbern California took place, the property sold being a two-thirde interest in the "Rattler" and "Bonanza King" group of mines in Providence Mountain district, hy Messrs. Boyer, Drew, Hasson and Osborne, through Mr. Gillette, to two New York corporations, receiving therefor, respectively, $100,000 for the "Rattler" interest, and $325,000 for the "Bonanza King" interest. Messrs. Boyer, Drew, Hasson and Oshorne retain a one-third interest in hoth mines. These gentlemen went to San Francisco thie week to make the final eettlements of the sale. Theee mines have only lately come into notice, hut hid fair to eoon gain a prominent poeition among the noted rich minee of the Pacific coaet. Providence Mountain dietrict is ahont 100 milee northeaet of Colton, in a direct line, hut hy the wegon road, ie very near 200 milos. There ie plenty of wood and good water, and everything ie convenient for the working of mille and the eetabliehment of a camp. It is the intention of the corporatione to have a 10-stamp quartz mill erected and in working order within 60 daye. There is now ahont 2,000 tone of ore on the dnmpe which will average $150 per ton, all of which ore hae heen taken out of the minee while heing prospected, from the ehafts, drifte, etc. No etoping whatever has heen done eo far, and thoneande of tone of rich ore are in sight. Ahout $60,000 worth of ore has been ehipped from the minee, which hae paid all the working expeneee so far. When we eay this ore wae hanled 200 milee in eacks on wagone, and then ehipped from this point to San Francieco hy rail to he worked, and a splendid return received over and ahove all expensee, some idea may he formed of the richneee of the high-grade ore.

The Atlantic & Pacific railroad ie eurveyed within eight milee of the minee, and when completed will furnieh eaey acceee to the camp. The partiee now in charge of the minee intend eoon putting a large force of men at work, and expect a camp of 500 or 1,000 minere will he eetahliehed there ineide the next eix months.—*Colton Semi-Tropic.*

The Engineer.

Railways as Civilizers.

It would be an impossible thing for a newspaper article to give even a faint conception of the results of the building of railroads. The last four decades have marked an era in human progress in this country in this respect equaled by nothing except the discovery of the art of printing.

Bring to the front the strongest emphasis every argument that can be urged against railroads, and yet the inestimable benefits to the country and to mankind outweigh them all. As a civilizer the railroad has no equal. Wildernesses disappear as if by magic, and the long lines of towns and villages stretching across the continent are the results of railroads. They advertise their lands, give accurate descriptions of them and distribute millions of circulars all over the old world, thus attracting a hardy immigration hither who convert the savage wilds of the West into blooming gardens. Suppose they do add wealth to their coffers, so does Uncle Sam by this increase of taxable wealth. It has not been many years since the maps, pored over by the school-boy, portrayed, sharply outlined, a vast, arid tract of country in the western plains, known as the Great American desert. Railroads penetrated it, people followed the railroads, irrigation was employed, and the man of to-day looks in vain for the terrible desert of his school days. The vast treasure caves of Colorado, Nevada and the West would still be sealed by the forbidding obstacles nature has interposed to guard her glittering stores, were it not for the magic influence of the railway lines which now rush over the deserts and plains and penetrate the vast and silent canyons of every mountain chain, unlocking the rock-bound caskets and bestowing the hidden treasures upon the hardy and enterprising seekers.

But the story is not yet half told. The limit of development is still far beyond human ken. There are depths yet unsounded, realms yet unexplored, which will in time respond to the shriek of the locomotive, and unfold untold riches to the explorer. So far civilization, development, wealth and refinement have been the results of railway extension into hitherto unknown regions to an extent that must overbalance the evils that many complain of. Every good is mixed somewhat with evil, but our country can well afford to put up with the crookedness of syndicates which have accomplished such wonderful work as the young West to-day presents.—*Exchange.*

TUNNELING HISTORIC GROUND.—The tunnel on the line of the New York, Ontario and Western railroad, through the Palisades, and connecting Weehawken to New Durham, touches historic ground at its eastern approach. Exactly over this spot is where Alexander Hamilton and Aaron Burr fought that famous duel that robbed the nation of its great statesman. Here also Burr fought John B. Church, and here were witnessed the following affairs of "honor": The duels between DeWitt Clinton and John Swartwout, Com. Perry and Cap. Heath, George J. Eacker and Philip Hamilton, Benjamin Price and Maj. Green, Wm. J. Graham and Mr. Barton, of Philadelphia, together with several contests of less importance. An effort is making in New Jersey to have a monument erected at this point to perpetuate the stories of the murders there perpetrated and the memory of those who participated in the bloody combats.

ELECTRIC LIGHT IN LONDON.—The present condition of the electric light in London is: Streets are now being lighted with it at one-fourth of the price of gas; incandescent lamps can be introduced into every room of any house so soon as the mains are laid; there can be a separate meter to each house; the lamps can be separately lighted and put out by turning a cock; if one light goes out no other one is affected; the subdivision is so complete that there is no glare, and yet a room with incandescent lamps is far more brightly lighted than with an equal number of gas lamps, and an equal amount of candle-power produced by electricity is cheaper than an equal amount produced by gas. In addition, the electric light has no odor, it does not vitiate or heat the air, nor does it, like gas, tarnish paint and decoration.—*Truth.*

A STONE BRIDGE, to be built at Minneapolis, Minn., bids fair to become one of the notable structures of the world. According to an exchange it will consist of 16 80-foot spans and four 100-foot spans, and, including the shore pieces, will have a total length of 1,900 ft. It will support two railway tracks at a height of 60 ft. above the water, and will run diagonally across the river below St. Anthony's Falls. The cost is estimated at nearly $500,000. This will be a remarkable bridge, truly; but so far as length of span is concerned, the Cabin John bridge, or Union Arch, near Washington, D. C., exceeds it, being a granite arch of 220 ft. span, the longest stone arch in existence. The bridge is 101 ft. high and 20 ft. wide.

TELEGRAPH MILEAGE OF THE WORLD.—A French statistician has calculated that if all the telegraph wires at present laid were tacked on end to end they would reach 46 times round the world. Belgium has a greater telegraph mileage in proportion to its superficial area than any country in Europe. Switzerland comes second and Great Britain third. Russia has the least.

Useful Information.

A Varnish for Ships, etc.

M. Ricarde-Seaver prepares a varnish for ships, etc., by the following process: One hundred lbs. of sulphate of copper are dissolved in hot water, and to the solution 30 lbs. of glucose are added. A saturated solution of 80 lbs. of commercial carbonate of potash is prepared and added in small portions to the first solution, till the quantity of pure alkali thus added has reached 30 lbs. (The carbonate of potash may be substituted by carbonate of soda, or another alkaline base, but, in general, potash is to be preferred.) The above mixture is heated to 212° Fahr., and kept at that temperature until, by the formation of precipitate, the color of the solution changes from greenish blue to yellowish red. The solution is then taken away from the fire, and the precipitate, which consists of a hydrated suboxide and an anhydrous suboxide of copper, is collected on a filter. It is then washed, and the water with which it has been washed is added to the filtered solution, which is again heated to 212° Fahr., and the precipitate now formed is filtered, washed and added to the first precipitate. The precipitates are now dried carefully, in order not to drive away the water of hydration, and is then mixed in an appropriate vessel with 2 lbs. of a solution of phenic acid, 75%. It is left to stand for about five hours, or until the color of the top of the mixture has changed from yellow to green, then heated not above 190° Fahr., until it becomes thick enough to be mixed with oil. The required quantity of linseed or other oil is then added. The sulphates of the alkali used, which are the result of the above reaction, can be utilized after crystallization from the residue water.—*Boston Jour. Com.*

A NEW, CHEAP AND SUPERIOR GAS.—According to the London *Times*, a great improvement in the manufacture of gas has just been introduced at Watford by Messrs. Rogers Bros., whose workshops and premises are now lighted with the new gas, which gives a pure white and brilliant light of about five times the illuminating power of ordinary coal gas. By the new process no smoke or smell is emitted, and no "scrubbing" or lime purifying is requisite. There is no danger in the manufacture, as only non-explosive oils are used. The new apparatus can be adapted to any existing coal gas works, and all ordinary pipes, gas-holders, etc., can be utilized. A sufficient quantity of gas of great luminosity and purity can be manufactured in a few hours to keep a large mansion supplied for a week at 1s. 6d. per thousand cubic ft., which is about one-third the price of the Watford town gas. A burner passing 1 cubic ft. per hour of this new gas, according to the photometric test, gives as much light as a burner passing 5 cubic ft. of the ordinary coal gas; and as it contains no sulphuretted hydrogen or carbonic acid, plants, pictures, hooks and gilding do not in any way suffer from its contact.

A SCHOOL FOR BRAKEMEN.—The Erie is fitting up one of the buildings of the new car shops at Hornellsville with an ingenious apparatus, with which their brakemen will be taught the management of the air-brake. The instruction is afforded by a set of air-pipes, equal in length to what is required for a passenger train of 12 cars. This is laid at a hight of about six inches from the floor, and three air-brake cylinders are connected with the pipes. The air-pump is fastened against the wall, and is operated by steam, which is carried through a pipe from a locomotive in the round-house. The model is perfect in all points, and its workings can be illustrated as clearly as if the brakes were attached to a train. It is believed that by familiarizing the brakemen with the air-brake, many accidents, due to the ignorance of its workings, may be averted.—*Buffalo Express.*

SOME REPRESENTATIVE AMERICANS.—The theory that the human race will not be able to maintain a high order of physical development on this continent did not receive much encouragement at a recent social gathering of "tall men" in New York city. The "Titans," a society to which only gentlemen of position and of a stature not below 6 ft. 2 inches are eligible, now numbers about 100 members, largely representative of our oldest and best known American families. Seventy-three Titans sat down together at the recent annual dinner of the society. The tallest measured 6 ft. 6 inches. There were a dozen generals and colonels among them, as many prominent physicians, and a long list of distinguished lawyers and business men.

DOUBLE HYBRID WORM-PROOF COTTON.—Mr. L. C. White, of Jasper, Jasper county, Texas, claims that after 20 years of study and experiment he has fully succeeded in producing a worm-proof cotton. Not only is the plant worm-proof, but it produces, he says, more and larger bolls to the stalk than any other cotton, matures earlier and has a better staple and finer lint than any other cotton grown. He wants the Government to pay him $1,000,000 for the seed and for his theory. If his "double-hybrid," absolutely worm-proof cotton is all he claims for it, he should be able to make $1,000,000 selling seed to planters much quicker than he is likely to get such a sum from the Department of Agriculture.

SPONTANEOUS COMBUSTION.—A New York artist relates a case of spontaneous combustion in his studio which is chiefly singular because the fire did not result more seriously. He had been staining his wainscoting with a preparation of Prussian blue, black oil, and turpentine, and threw the cloth which he had used on the lounge, first wrapping it in a piece of burlap. During the night the cloth lighted spontaneously, burned through the burlap and the covering of the lounge, and destroyed one of the hard wood arms. These cases of spontaneous combustion are not rare, and, while it is not generally admitted, there is no doubt that the burning of many a furniture factory can be traced to the careless disposal of rags which are used in staining and finishing. They are often seen smoking in an ordinary basket and slowly burn away. A sheet-iron box to put them in would do away with any danger, and avoid the occurrence of "many mysterious fires" by probable incendiaries.

SEASON FOR FELLING TIMBER.—I have been watching the wood department of the paper to see if any one has anything to say with regard to the proper season of the year to cut timber; but as yet I have noticed nothing upon this subject. My experience and that of those who have preceded me, for the rule has been handed down for at least three generations, is that the very best season for felling timber is in the old of the moon in February. Timber cut at that season will outlast that which is cut in other months. Further, I will state that my experience is that timber cut in June has the shortest life of any. I shall be glad to hear from other readers on this same subject.—*Blacksmith and Wheelwright.*

PRINTERS' INK FROM COTTON WASTE.—M. Bastand subjects cotton waste, in a closed vessel, to the action of bisulphate of carbon, or any other liquid having great affinity for oil and capable of evaporating at a lower temperature. Bisulphate of carbon is, however, to be preferred on account of its cheapness. It should completely saturate the cotton contained in the vessel, and run off with the oil and grease of the waste into a suitable receptacle, in which the mixture is subjected to the action of heat. The bisulphate of carbon is evaporated and condensed, to be used over again, and the oil and grease serve admirably for printers' ink, while the cotton waste, deprived of its grease, is as useful as before.

REMEDY FOR CLICKING.—The best remedy that I have ever found for horses clicking or striking their hind shoes against the forward ones is to put on high toe-calks and low heels on the hind shoes. If my brother smiths are incredulous concerning this remedy, I advise them to try it and be convinced.—*Blacksmith.*

STEAM PIPES RUSTING INSIDE.—It is often found that steam pipes and fittings corrode badly on the inside, so much so that leaks are sometimes formed. This action is generally attributed to the presence in the steam of much free oxygen and carbonic acid and sometimes sulphites—derived from sulphides present in the water.

Good Health.

"Cold Catching."

It is noteworthy as a curious yet easily explicable fact that few persons take cold who are not either self-consciously careful, or fearful of the consequences of exposure. If the attention be wholly diverted from the existence of danger by some supreme concentration of thought, as, for example, when escaping from a house on fire or plunging into cold water to save life—the effects of "chill" are seldom experienced. This alone should serve to suggest that the influence exerted by cold falls on the nervous system. The immediate effects of a displacement of blood from the surface, and its determination to the internal organs, are not, as was once supposed, sufficient to produce the sort of congestion that issues in inflammation. If it were so, an inflammatory condition would be the common characteristic of our bodily state. When the vascular system is healthy, and that part of the nervous apparatus by which the caliber of the vessels is controlled performs its proper functions normally, any disturbance of equilibrium in the circulatory system which may have been produced by external cold, will be quickly adjusted. It is, therefore, on the state of the nervous system that everything depends, and it is, as we have said, on the nervous system the stress of a "chill" falls. Consciousness is one element in the production of a *cold*, and when that is wanting the phenomenon is not very likely to ensue.

It is in this way that persons who do not cultivate the fear of cold-catching are not, as a rule, subject to this infliction. This is one reason why the habit of wrapping up tends to create a morbid susceptibility. The mind, by its fear-begetting precaution, keeps the nervous system on the alert for impressions of cold, and the centers are, so to say, panic-stricken when even a slight sensation occurs. Cold applied to the surface, even in the form of a gentle current of air somewhat lower in temperature than the skin, will produce the "feeling" of "chill." Conversely a thought will often give rise to the "feeling" of cold applied to the surface—for example, of "cold water running down the back." Many of the sensations of cold or heat which are experienced by the hypersensitive have no external cause. They are purely ideational in their mode of origination, and ideal in fact.—*Lancet.*

Ventilation and Fresh Air.

Fireside comforts are almost inseparable from the idea of an open fireplace, and from a hygienic standpoint, too, the old-fashioned chimney, or an open grate, is far superior to a closed stove. But it should not be forgotten, writes Dr. Oswald in the *Popular Science Monthly*, that the operation of the chimney-draft alone is insufficient to correct the vitiated air of a small room; it merely creates an outward current. An open window completes the renovating process; in cold weather a few minutes are sufficient to revitalize the indoor atmosphere for a couple of hours. Only the blindest prejudice can deny the pleasant effect of such an influx of life-air; it revives the azotized lungs as a draft of cool water refreshes the parched palate. Colds are never caught in that way. The very name is a misleading misnomer; inflection or influenza would be the right word. Long exposure to a freezing storm, in certain cases, induces a pure pleuritic fever—a very rare affection, and entirely different from the only too familiar catarrh.

What we call a cold is caused by the influence of impure air, or dust, on the sensitive tissue of our respiratory organs; subsequent exposure to the open air merely intimates the crisis of the disorder—the discharge of the accumulated mucous through the nose or throat. Fresh air is here only the proximate cause, as in toothache, or in those paroxysms of retching following upon the first respiration of a half drowned person. If we postpone the crisis by persistently avoiding the open air, the unrespirable matter, instead of being discharged, will be deposited in the tissue of the lungs in the form of tubercles.

STOMACH DIGESTION.—After thorough mastication, each mouthful of food is in turn swallowed, being drawn down into the stomach by the muscles of the œsophagus, not simply dropping into that organ through the open tube, as many people suppose, the œsophagus being always closed, except that portion which is occupied by the food in its passage to the stomach. Shortly after the food has reached that organ, its mucous membrane assumes a rosy appearance, and then may be seen, oozing from its surface, the gastric juice in tiny drops, like perspiration on the skin. The secretion increases rapidly, and begins at once its specific action on the albuminous elements in the food. It may occur that the gastric secretion has been excited before the food has been swallowed, in which case there is no delay whatever in the commencement of gastric digestion. All this has been learned from observations in the curious and well known case of St. Martin, whose stomach, by a wound, was opened to view, and was continued in that condition for a number of years. If the stomach contains a large amount of fluid, that must first be absorbed before the digestive process begins. Hence the propriety of using but little liquid while eating.

IMPORTANT MEDICAL GAIN.—The one great medical discovery that will serve to distinguish the year 1881, is that of Pasteur, the great French chemist, of a method of mitigating the malignity of the virus of certain fatal contagious diseases among domestic animals, which diseases have hitherto defied all curative treatment. Pasteur has demonstrated by these brilliant and convincing experiments that he has succeeded in effectually controlling these virulent diseases. He has been able, by subjecting the virus of the disease to certain processes, to so modify it, that when introduced into the bodies of healthy animals—as in vaccinating the human subject—it produces but a temporary indisposition, and thereafter renders the inoculated animal effectively proof against the disease. The enormous money value of this great discovery to the agriculturists of Europe, who have been great losers by the ravages of disease among their flocks and herds, is admitted. But still more valuable results may, and probably will, flow from it by the extension of the discoverer's method to the protection of the human subject against many malignant and fatal diseases that afflict the human kind.

ANTI FAT DIET.—Dr. George Johnson, in the *Practitioner*, proposes the following as an anti-fat diet: May eat—Lean mutton and beef, veal and lamb, soups not thickened, beef tea and broth, poultry, game, fish and eggs, bread in moderation, greens, oresses, lettuce, etc., green peas, cabbage, cauliflower, onions, fresh fruit without sugar. May not eat—Fat meat, bacon or ham, butter, cream, sugar, potatoes, carrots, parsnips, rice, sago, tapioca, macaroni, custard, pastry and puddings, sweet cakes. May drink—Tea, coffee, cocoa from nibs, with milk but no sugar, dry wines in moderation, brandy, whisky and gin in moderation without sugar, light bitter beer, soda and seltzer water. May not drink—Milk, except sparingly, porter and stout, sweet ales, sweet wines. As a rule alcoholic liquors should be taken sparingly and never without food.

Passing Events.

From all quarters we now hear reports of a prosperous outlook for the coming season. The miners in this State hope to do well this year, the only thing now feared being an adverse decision in the debris case. Judge Temple has not yet rendered any decision, and of course everything remains in a state of doubt.

The people of the Pacific coast have been in a fever of expectation during the past week on the subject of the Chinese bill. As we write (Thursday afternoon), the matter is still pending. Meantime many Chinese are coming and many more are getting ready to come.

Spring is now at hand, and the prospectors are preparing for active work in such regions as are not covered with snow. Before many weeks the hills in all the newer mining districts in the country will be visited by men in search of new mines. We hope to chronicle many new discoveries.

THE piers for the Northern Pacific Railroad bridge across Lewis Fork (or Snake river), near its mouth, will be eight in number and will cost $250,000. The entire superstructure will be of the best quality of iron, and constructed in the most substantial manner. It will cost not far from $500,000.

NICKEL AND COBALT.—The second paper on this subject, to follow the one published last week, will appear in the next number of the PRESS.

Prospectors and Miners.

This month will see thousands of prospectors starting out for their summer's work in the mountain ranges of the Pacific coast. In some regions, where snow lies long, they will be late in beginning; but in all the camps preparations for the summer's campaign will soon begin. It will not be long before reports of rich regions will come in, and we shall be pleased to chronicle the numerous finds that will be made.

But it does not by any means follow that, because new districts will be found, they will be much better than old ones. True, the first men in a new district get a chance to take up a lot of ground; but that is no reason men should drop claims they have to rush off after new ones that may be no better.

If a miner has a pretty good prospect in hand, be can seldom do better than by holding on to it and proving it up. There is no need, when a man has a good claim, of rushing off to every new camp discovered, and keeping up a wild goose chase all summer. Too many men do that. Let every man be a prospector until he finds a claim. Then turn miner and do something with it. If the claim proves bad, or can be sold, then turn prospector again. But a man who is always a prospector and never a miner seldom makes much money.

Then, again, there are fields of exploration close at hand, which may be better than those farther off and more talked about. The old saying of "Distance lends enchantment," is never better verified than in the case of the prospector.

He imagines, if in Arizona, that there are better chances for prospectors up in Idaho or Montana and an easier country to work in. If in Montana or Idaho, he thinks, perhaps, Arizona or New Mexico offer better fields for his energies. If in California, he thinks that State played out, but away from it he thinks "old California a pretty good place to tie to after all." In fact, while he swears by the claim he happens to have in hand at the time, and thinks it promises better than any he ever had, he also thinks some other country better than the one he is in.

The influence of habit makes the old prospector restive. A few times over the same ground gives it a played-out look to him. He sighs for new regions, new surroundings and a change of base. He eagerly listens to all that is told about newly discovered regions and swallows stories that sober reasoning and thought tell him cannot be true.

Men will drop claims and leave for new districts to take up claims not worth half as much, and defend their judgment by sticking to the last location till they can hold on no longer. The fascination of a new camp is one that the prospector finds it hard to resist; and when half a dozen men leave a camp for a new one, half of those left begin to think about it too.

Of course, no amount of advice would accomplish much. Each man knows what he wants better than any other man. Prospectors will keep on roaming and changing till time is no more. But perhaps some who have been prospectors will rest content when once mining the claims they have found, and accumulate some of the money which too often falls to the lot of those who do no work, but profit by the nomadic habits of those who find the claims.

ALASKA MINES.—Advices from Harrisburg to the 17th of March say: The steamship, *Eureka*, arrived here this morning and landed a large quantity of freight, and then steamed over to Douglas island and landed a quartz mill for Mr. Treadwell. He has also a large gang of men at work getting things cleared away and making ready for putting up the mill. We have had a considerable fall of snow this last month. There is at present about 30 ft. of snow up on the mountains. It has been blowing a gale from the north for the last week, and the weather is quite cold at present. Fuller has struck the ledge in his mine after running a tunnel. He had cut in on the ledge 11 ft., and had not found the opposite wall. The ore looks well and shows free gold all through. Everybody in camp is feeling jubilant over the rich prospects. The only thing we are in need of now to make this one of the most prosperous mining camps on the Pacific coast is civil government, law and justice, so that capital will have some protection. If Congress thinks it can't afford it we would suggest that the Territory be given back to the Russians.

YOSEMITE VALLEY.—The Yosemite Valley Commission met on Monday afternoon, and decided to purchase the Glacier Point trail, and make it free to the traveling public. A communication has been received stating there is nearly five ft. of snow in the valley, and that the wind has made severe havoc among the trees in one spot, just immediately under Glacier point. Large pines and cedars, from two to four ft. in diameter, have been broken off like pipe-stems; others were uprooted. Large limbs have been wrenched off and hurled into and across the road. Destructive as this wind was, it has opened up one clear spot for the better view of the grand wall of Glacier point, leaving timber and firewood for the valley's use. The mail carrier reports from 12 to 15 ft. of snow on the mountains, so that the falls will be exceeding grand this spring and summer.

Production of the Precious Metals.

An Abstract of the Census Monograph on the Bullion Output of the Country.

Second Paper.

But the impossibility of assigning to other channels the due proportion of the outflow through them; the fact that no record is made of the value of the gold bullion and dust sent through the mails; that no reliable allowance can be made for the undervaluation of gold dust and unassayed bullion by consignors, amounting in many cases to from 5% to 10%; that there is no satisfactory means of checking the re-shipments which are twice or more times recorded, combine to create a large margin which can hardly be definitely accounted for in making the total estimates. The looseness in the distinction observed between silver bullion and dore metal allows a considerable portion of the gold contents of dore bullion to escape the record, the whole value of such bars often being credited to silver; while, on the other hand, of course no account is taken of the value of the silver alloyed with placer dust and gold bullion, though this is a less important source of error. Notwithstanding these palpable but unavoidable defects in the system, much credit is due Mr. Valentine for the painstaking care with which he has prepared his annual estimates.

The third system is one which, were it practicable to pursue into complete details, would lead to results more satisfactory than could be obtained in any other way. This may be termed the direct method. It would consist, if properly carried out, in obtaining from each bullion producer a statement of the quota contributed. The aggregate of the details thus reached would represent the actual total product of the country, and would, moreover, segregate it according to districts. In the census work conducted by the U. S. Geological Survey, the plan indicated has been followed to as minute detail as it was possible to extend it with the means at command. No attempt had ever been previously made which aimed at securing individual returns throughout the whole United States with the same degree of thoroughness; though the successful adoption of the direct method by Mr. A. Del Mar, in his investigation of the silver product of Nevada in 1876, showed the advantages of the plan. But even with all the time and care expended by the experts engaged in collecting the statistics, it was found to be impracticable to do more than obtain returns from the larger producers. In some instances well-based and careful estimates were submitted by the experts, covering aggregates of a large number of small mines, for whole districts. In other cases, and more especially so in portions of the country where placer mining on a small scale furnished a large proportion of the yield, reliance had to be placed on extraneous data.

The chief obstacles encountered in the collection of bullion statistics directly from the producers were:

First. The wide extent of the field to be covered and the vast number of mines to be reported upon, even were the mines located in easily accessible places, the wide range of territory over which they are scattered would render the labor of personally visiting each productive district a tedious matter. But when it is considered that they are for the most part to be found in rugged, mountainous tracts, often at high altitudes, and, when destitute of railroad communication, to be reached only by stage or on horseback, some idea may be gathered of the amount of work involved.

Second. The fact that a considerable yield is derived from small mines, the product from each of which, however insignificant in itself, goes to form part of an important aggregate, and should not be neglected.

Third. The reluctance of some mine owners and superintendents to give a full account of their operations, notwithstanding the strictly confidential manner in which these individual statements have been treated. On explanation of the purposes for which the statistics were collected, such objections were in most cases overruled, however, and invariably great courtesy was personally manifested.

Fourth. The fact that in a large majority of cases no systematic accounts are kept by mine owners, who were often unable to state from memory the precise output of their properties for a period which had elapsed some time before the inquiry was made.

Fifth. Many mines having changed hands during the census year, it was frequently impossible to obtain from the present holders a statement of the operations conducted prior to the change in ownership, or to communicate with the former owners, if they had removed.

Sixth. When in the case of mines worked during only a portion of the census year, or during a season limited by the weather, water supply, or other causes, operations had been suspended at the time the district was visited by the examining expert, it was often impracticable to communicate with the only persons able to supply information.

Seventh. The variation in the fiscal year of the incorporated companies makes it a matter of much difficulty to reduce the returns to a different period from that for which the books are kept.

With means still less adequate than were lately at command, the census authorities in 1870 found it impossible to trace the bullion product of the country at that time. The best results reached by the depoty marshals in certain instances hardly amounted to a moiety of the actual product, as known through other sources of information. In the case of the census of 1880, even with greatly increased facilities, there were many gaps in the testimony which had to be filled out by estimates derived from other data than those collected directly by the experts. Where such estimates have been applied in the tabulation, they have been indicated by an asterisk (*). In all cases a careful scrutiny has been exercised in the selection and comprison of material. It is believed, in view of the more extended and fuller details accessible, as compared with previous researches of the same nature, that the results arrived at in this compilation are as close an approximation to absolute accuracy as it is possible to attain without a far greater expenditure of money and time than the subject demands.

In compiling the material at hand this following system was adopted: The returns given in the individual mine schedules were first abstracted and grouped into aggregates for districts. Information as to the operations of the different establishments being in many cases confidential, publication of the results begins in the census report with the district exhibits, which, in the following pages, have been condensed into tables for counties, and finally into abstracts for whole States and Territories. Where a marked discrepancy existed between the schedule returns and other reliable data, the necessary additions were entered and the fact that they were estimates indicated. It is hardly necessary to remark that the schedules would show deficiencies rather than an excess as compared with correlative data. At the same time the schedules of reduction works were examined, and furnished a valuable check upon the figures derived from the mine reports. In some instances the yield was quoted in ounces of fine metal, as is customary in localities where the ore is reduced by smelting; in others, in ounces of crude bullion, as in the case of placer gold; in still others, in dollars, calculated from the assay value of the bullion; and more rarely, in dollars, representing the net proceeds after deducting the discount upon silver and other charges. In order to present the whole in harmonious shape, it became necessary to reduce these various denominations to a uniform standard. That adopted is the Troy ounce of fine metal and its assay value in United States money. In the following tables, however, the bullion product is quoted in dollars, disregarding the weights.

Classification of Mines.

Mines of the precious metals are grouped under two comprehensive heads: deep mines and placer mines. The former are workings in primary deposits, in which the ore usually, though not invariably, occurs in a vein, and while the earlier operations in mines of this class may begin at or near the out-crop of the vein, the tendency is always downward. The leading varieties of deep mines are:

1. Mines of free gold, or gold alloyed with a small proportion of silver.
2. Mines of silver ores, containing only traces of gold.
3. Mines yielding dore bullion from milling ores containing both gold and silver in appreciable quantities.
4. Mines yielding base bullion from smelting ores in which the precious metals are associated with larger quantities of lead, copper, etc.

All these divisions shade imperceptibly into each other.

Placer or gravel mines are workings in secondary or fragmentary gold deposits, including gravels and sands, and are either surface or shallow workings. The leading types are:

1. Hydraulic mines.
2. Dry washings.
3. Booming and shovel-sluicing.
4. River mines.
5. Pocket miner.
6. Drift mines.
7. Branch mines.
8. Black sand littoral deposits.

In the tables of production the classification under these two main heads is observed.

Classification of Reduction Works.

In some of the following tables a distinction is made between the production as shown by the different reduction works, which, like the mines, are divided into two principal classes. These are, first, amalgamating mills, including—

1. Gold-quartz mills.
2. Mills in which silver ore is treated in the raw state.
3. Mills in which roasting is practiced before amalgamation.
4. Concentration works.
5. Chlorination and leaching establishments.
6. Arastras.

The second class includes the several varieties of smelting works in which the production of base bullion, matte or speiss is a preliminary step toward the final extraction of the precious metals.

(TO BE CONTINUED.)

FEARS have been freely expressed, says the Eureka *Sentinel*, that our two representative mines were pinching out. The figures will not bear out such an assumption. During January and February the Richmond shipped $205,279 in bullion, and during the first 11 days of the present month the Eureka Con. turned out $51,128.51. Considering the comparatively small number of men employed, it is one of the best showings ever yet made.

Mammoths.

(Continued from Page 209.)

fonnd mammoth, was at that time generally discredited.

The Moet Celebrated Discnvery

Was made in 1799. A Tungusian fisherman named Schnmakoff was exploring along the coast of the frozen ocean for ivory. He was near the month of the river Lena, in latitnde 70°, when he discovered in a huge block of ice a dark, mis-shapen mees whose natnre he could not clearly make out, as it was too deeply imbedded. But it had two great tusks of ivory which he greatly coveted, hnt could not then detach. Cold seasons followed, and it was not till five years later, in 1804, that he reached the spot again. Then he foand that the ice bank had melted, and the mammoth, for snch the great object proved to he, had fallen ont by ite own weight. He cut off the tnsks, which he took on a long journey south, to Jakutsh, and sold to an ivory dealer. It so happened that a few yeare later, 1808, an English traveler named Adams, visiting that city, saw the tusks and heard the etory of thsir finding. He orgaaized a psrty and retnrned with the Tnngusian to the place where the latter had fonnd the great beast. But it was no longer complete; for in the years which had intervened since the first discovery, the nomadic trihe, Jakntski, had been feeding their dogs upon the flssh, which they cnt off for the pnrpose. Also the wild beasts of the region, the white bears, wolves and foxes, had come in for their share of the food, and had dragged the bones aronnd and trampled the hair into the snrface earth. Adame collected with care this skeleton, which, although mainly cleaned of flesh, lacked but one fore-foot of being complete. He also took the skin of one side of the great creature, with about forty pounde of the loag black hair and undercoating of reddish wool which covered it. At Jakutsk he was so fortnnate as to secure, by purchase from the ivory dealer the two great tusks. The next year he transported the whole a weary jonrney of 7,000 miles to St. Petersburg, where the precious relic was purchased for 8,000 roubles hy the Emperor Alexander and placed in the musenm hall of the Imperial Academy of Sciences. The great animal still stands there monnted—a hnge skeleton, with skin over parts of ite head and one leg, and the hair still adhering in places.

The Mnsenm of Natural History in Paris and the Royal College of Surgeons in London were each presented with portions of the skin. Such is, in hrief, the etory of

The Siberian Hairy Mammoth,

(Or the "St. Petersburg Mammsth") as it is often called. This specimen, with the two others mentioned first as having been found in the same conntry, stands nnique in the whole history of fossil remains in the fact of the preservation of the soft parts of tbe animal—its flesh and sinews—in connection with the bones. Snch an occnrrence is phenomenal in the most extreme degres, and only its most complete authentication, by the preservation nf the specimen itself, has secnred acceptance and belief. To account for thie phenomenon, geologists biased more or less by the known hehits of living elephants, which are restricted to tropical regions, have hed reconrse to the hypothesis of a

Cnmplete Change nf Temperature,

Either snddenly brought about by a great geological cataclysm, or due to the secnlar changes of land and sea level, which bave ever been at work in the past as at the present dey. Unquestionably, the intense and possibly increased cold of that northern region has heen the canse of the preservation of theee remains. But the heavy coating of hair and wool, so different from that of its modern elephent congeners, indicetes clearly that the mammoth was adapted for life in these cold regions, where it roamed in herds and was a permanent resident. The fact that the rhinoceros found here should also have heen clothed with thick hair, while its modern relative in tropical regions ie as naked-skinned as the elephant, is an additional and powerfal argument for the belief that the climate of northern Siberia was of its present winter severity at the time that these great pachyderms lived there. The fact seems to have been generally overlooked that an animal, organized as the teeth of the mammoth plainly indicate, to gain its subsistence from the braachee or woody twigs of trees, is thereby rendered independent on the proceseion of seesons which regulate the development of leeves or fruits. The food of such an animal is perennial, to be obtained ae easily during the months when snow covered the whole plain, as during the shorter period when the surface of the country was green with its transient summer coating of ehrnbs, moss and lichens. Any animal clothed like our mammoth, or like the reindeer of Greenland, with a natnral garment cepable of

Resieting the Rigors of an Arctic Winter,

Would have fonnd permanent pasturage on thsse inclement and desolate plains which lie across all Siberia between the 60th parallel and the perpetnally frozen ehores of the icy sea. Forests of hardy shrubs still cover the frozen soil of this portion of Siheria, eo the qneetion of food for eo migbty an animal really preeente no difficnltiee whatever. Had onr knowledge of the mammoth, indeed, been restricted, ae in the caee of all other extinct animale, to ite bonee and teeth, the analogy of theee witb the modern elephant would have made it a hazardone epecnlation to have conceived, *a priori*, that it had a clothing so different as to euit it to this aorthern residence. The actual fiading has settled this difficnlty, and shown ue that here, as in many other cases, the proven facts nf natnre oatstrip the ventures of reasoniag.

The pecnliar

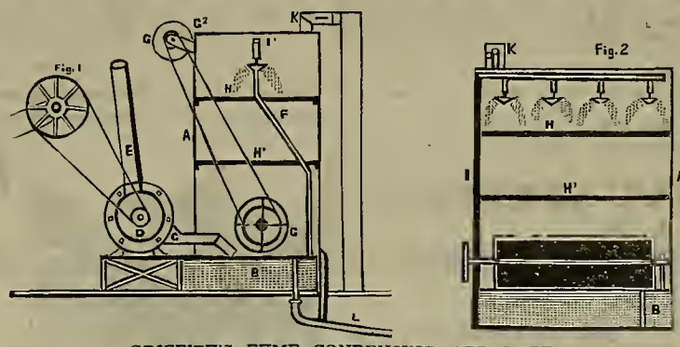
Physical and Climatic Cnnditinns

Of the region where these frozen mammoths have been fouad give ns a not difficult or improhable solntion to their strange entombing. It will he remembered that the country is, in its general aspect, a broad plain, more than 1,000 miles wide, traversed hy great rivers which rise in the higher and warmer regions more than 20° of latitude to the south. In the early spring these rivers in their upper oonrses at the south, send down a freshet of water, which, ae it reachss the lower conntry, finde the bsd of the stream still bound in solid ice. Over this ice, over the banks of the river, the waters, pressed on from behind, force their way, and, spreading over the entire coantry on either side, change it to an innndated plair, nntil limited to the north by a line where the water steedily freezss, and fnrther progress is stayed. Along this line, waving with the conformation of the surface and oscillating with the period of the year, the wandering mammoths were expressly liehle to he caught aad entrapped in the delnge of freezing water. Thns frozen in, and entirely enveloped with a thick covering of ice, some have, as we have seen, remained covered until the present day and their flesh conseqnently preserved. That hy far the greater number of the great herds shonld have left us only their bones, teeth and tusks, is furthermore in fnll accordance with the fact that most of them died an ordinary death, with the climate at a temperature which was insufficient to preserve their carcasses. Those which were overwhelmed and entangled in ice were the exceptions.

In Europe, at least, the mammoth seems to have been

Cneval With Early Man.

In the bone caverns of England, France and Germany, those great charnel houses of early animal life, there are found scoree and hundreds



GRIFFITH'S FUME CONDENSING APPARATUS.

of hones of the mammoth commingled with those of the rhinoceros, hippopotamus, aurochs, cavern bear, and other animale now quite extinct, or living in other continents. It is clear that the mammoths did not themselves crawl into tbese caves, often with an exceedingly narrow opening, and die there; nor do the surroundings often allow the idea that they were brought there hy a flood of waters. In many cases the abundant marks of teeth and the gnawing of the bones sbow that tbey were dragged to tbe cave by wild beasts that made it their den and fed upon tbem. But in a few epecial cases the cavern has been the home of early man, who brought there the remains of animals which they bad hunted and killed.

In These Caves

There are found, with those of other animels, maay bones of the mammoth, and of these, evory long hone has been split open to obtain the marrow from the central cavity.

Mingled with these hones are fonnd here and there the flint knives and stone hatchets which served as utensils at these early feasts. On a tusk of a mammoth found in one of the caves of Dordogne, in eonthern France, was a rude engraving of the animal itself, scratched long ages ago with the sharp point of a flint. These troglodytes are now no more. They and their giant neighbor, the mammoth, bave perished, one after the other, in the lapse of infinite ages, hy those changes of circumstances in the organic and inorganic world which are always in progress. No less tban 30 species of these fossil elephants—mammothe and mastodons—have been found in various parts of the globe, under nearly every parallel of latitude and in every continent except Australia. As an individnal form, the mammoth is nniquely interesting, as showing the maximum of size to whioh terrestrial animal life has ever attained. So large an organism reqnired an abundant and constant supply of food. This it obtained, as its teeth have shown us and as we see from its congeners, the elepbants of the present day, from the tender branches of trees and the succnlent stems of shrubs.

A Specimen nf the Allied Mastodon,

Dug up many yeare ago in the neighborhood of Newhnry, on the Hudson, contained between the ribe, in the region of the stomach, nearly a bushel of cbewed twige, the last meal of the great arbivore. Like modern elephants, the mammotha and mastodons liked to visit marehy places and poole of etanding water, to cool their hodies aad free themselves from ineects. It was in their visits to these swamps that many of them met their death hy sinking so deeply in the mire that it bscame impossible for them to extricate themselves. Thns engulfed, their bony framework, bared hy decomposition of the surrounding flssh, sank still deeper, and there, beyond reach of further disintegration, they have remained through maay ages to the present day.

Several skeletons have thus been found burried in clay or in peat marshes. Generally, however, only isolated honss are found—a thigh-hone, a shoulder-blade, some vertebras, a jaw or teeth. Thsre is hardly a county, not of prairie land nor yet absolutely mountainous, in ths entire Union where some mammoth or mastodon remaias have not been found. The soil of the Pacific slope contains them in abundance; so all the States hordering on the Missouri and Mississippi rivers for their entire length. The valley of the Ohio was followed by them in its entire lsngth, so the Susquehana, the St. Lawrence and the Hudson. Big Bone Lick, in Kentncky, was a favorite resort for them, and there, within an area of less than 100 acres, have been found huried in the mnd the hones of several hundred individnels.

These facts show that the mammoth end the closely allied

Mastodnn Once Rnamed in Large Herde

Over our whole country at a psriod eo recent that little chsngs in the configuration of the surface has since occurred. These great herds of elephants have forever disappeared from the surfacs of our soil, while their early compaaions, the huffalo, the elk and the deer, still remain, though in steadily decreasing nnmhers. It is hardly donhtful that they were coeval with our red hrethren, although the number of traditions referriag to them is not large.

In exhuming, in Missouri, a fine, perfect skeleton of the mastodon which now stands in the halls of the British Museum, Dr. Koch fonnd, directly under ite shoulder-blade a etone arrow-h ead, which, from its position, wae apparently shot into the thick skin of the great animal while alive, perhaps in a simultaneous attack of aborigines, who, by ahundant wounds, caused its death.

In the State of Wisconsin, as is well known, are meny large mounds of earth, some of them covering several acres, and huilt in imitation of the forms of various animals. One of these in the neighborhood of Racine, called "Elephant Mound," has the well-defined outline of a mammoth or mastodon with his long trunk. The likeness is unmistakable, and there can hardly be a reasonable donbt that the great animal himself was present se a model and inspired the construction.

The general intelligence of the early settlers of our country hae prevented many

Wild and Superstitinus Stories

Abont these great bones from heing rife in America. No one mistakes them for the hones of giants, nor attrihutes them to the Behemoth of Joh or to the ship-wreck of Noah'e ark. Not so in Europe. There, for many centuries, the bones of these harmlese proboscidians have figured largely in tbe demonology and gigantology which have had an accredited place in the lore and the literature of the people. Many an old work in bleck letter told in voluminous latin pages the long story "*De Gigantibus et eorum Reliquiis*," "*De dentibus gigantorum*," "*De gigantium osssibus*," and all the other marvels of this wonderous race.

For the information contained herein we are indehted to Prof. Henry A. Ward, who made at his natnral science establishment in Rochester, N. Y., the restoration of the mammoth now on exhihition in this city at tbe Mercantile Library Hall, Bnsh street. Strenuous efforts are now being made hy the Academy of Sciences to raise sufficient money to purchase the whole collection and keep it on this coast. It ie greatly to he hoped that the Academy will succeed, as it would be a pity to see the unique collection depart from our shores. Over 5000 people a day have visited the hall since the Ward collection hae been on exhibition. The main interest hae centered on the mammoth, and we take pleasure in giving an engraving of it, eo that those in the interior nnable to eee the epecimen, may have eome idea of its appearance. Ite great eize may be imagined by comparing it with the figuree of men and horse in the engraving. The height is 16 feet, and length, inclnding forword curve of tuake, 26 feet.

Apparatus for Condensing Fumes.

Gases from metallargical fumes have generally heen condensed and the smoke therefrom pnrified by passing them throngh a spray of water, and through water droppiag from partitions placed on the condenser, as shown in Johnson's arrangement, patented Feb. 18, 1873. It has also been customary to inject the gases from such furneces into a vessel containing weter, or other liquid, by means of a wheel placsd in said reeervoir, as shown in the patent of R. C. Bockiag, of July 3, 1866.

A. E. Griffiths, of Philadelphia, has recently devised an apparatus for condensing fnmes, to be used in connection with fnrnaces, retorts, etc. The arrangement is an improvement on a patent granted to Mr. Griffithe March 27, 1866. The vapors are condensed and metellio particles saved.

Figure 1 of the engraving is partly in section, and shows a reservoir for the reception of gasee arising from metallurgic furnaces and fumes arising from retorts and kettles, in whioh chemicels are treated and tallow and other substances rendered, a fan for drawing the gasee and fumes from the furnaces and forcing them into the condensing reservoir, pipes through which the gasss and fumes pass to and from the fan, a water bath within the reservoir, a rotating aire gauze, screen for agitating the gases and fumes, and pipes for conductng the water to and from the reservoir. Figure 2 is a transverse sectional elevation, ehowing the devices for producing a ehower hath for the gases and fnmes within the reservoir.

In constructing devices of this character, there is provided a reservoir, or what may he termed a condensing tank, *A*, in the lower portion of which there is maintained a bath of water or other liquid, *B*, into which any particlss of metal which may be carried into it from a metallnrgic furnace by the escaping gases, fall, and from which they may be removed from time to time through a men-hole or other snitable opsning. Into this bath the gases from the furnaces and the fnmes from other devices are also carried through a pipe, *C*, the outer end of which is attached to and in communication with a fan, *D*. This fan is driven hy any prime mover by means of belts, as shown, or in any other convenient manner.

The arrangement of the fan, *D*, and of the whole apparatus, with reference to the furnace, retort or kettle in connection with which it ie to be used, is such that the pipe, *E*, which leads the gases and fumes to it, may be attached to the top of the furnace, so that the fan may take away snch gases and fumes and force them through a pipe, *C*, into the hath of water in the reservoir or condenser, *A*.

For the purpose of agitating the gases and vapore ae they arise from the beth, there is placed in the reservoir, *A*, a rotating screen, *G*, which is driven by a pulley placed upon its outer end, around which passes a belt which extends to and over a pulley, G^1, placed upon a shaft journaled in bearings attached to the reservoir, *A*, upon which last-named shaft is a pulley, G^2, which may be driven by a pulley on the shaft of the fan, or by any other suitable means.

Above the rotating screen there are two or more wire-gauze diaphragms, *HH*, which extend across the reservoir, and are for the purpose of subdividing the gas and vapors as they ascend, so that they may he condensed hy being brought in contact with shower baths of water introduced through a pipe, *I*, the outer end of which may be connected to a pump or other source of supply. This pipe extends across the reservoir, within the same, and is provided with a series of outlets, I^1, which conduct water into a trough, pipe or a series of cups suspended from the reservoir, and from these water falls in the form of a shower hath upon the diaphragm, *H*, through which it passes through H^1, and falls into the lower portion of the reservoir, *A*, in doing which a portion of it comes in contact with the revolving screen, *G*, by which means it is sprayed among the ascending gases and fumes which are, to a great extent, condensed thereby and hy the falling water hefore it reaches the screen.

The wire gauze diaphragms have the effect of retarding the ascent of the gases and vapors, as well as to comminute the falling water and thus to hring the two bodies into more iutimate contact with each other, and so facilitate the condensation of the former.

For the purposs of conducting off the gases and vapors, should any remain uncondensed, there is placed upon the upper portion of the reservoir, *A*, so ae to communicate with the interior thereof, a pipe, *K*, in which is a valve; this, when desired, permits whatever may remain uncondensed in said reservoir to escape into the chimney of the furnace, or it may he conducted to the furnace and caused to pess through the incandescent fuel upon its grate, and thus he prevented from producing auy injurious effect upon the vegetation of the surrounding country, and from annoying or injuring the puhlic.

As a means of preventing the water from rising too high in the reservoir, *A*, there is provided an overflow pipe, *L*, which rises to the required distance therein, or is attached to the outside thereof, at the requisite hight, eo thet when the water reaches the open mouth thereof, it will flow out, and thus the requisite amount of water is maintained therein, while it is prevented from rising too high.

CHICAGO **FRASER & CHALMERS,** ILLINOIS.

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furneces.

SMELTING FURNACES,

Water Jeckets, either Wrought or cast iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. B. Heggin for Giant and Old Abe Co., Black Hills also Corliss Pumping Engines, 26x60, for Hoisting and Pumping Works, for 2,000 feet deep. **Baby Hoists for Prospecting, 4 H. P. to 6 H. P.**

Wire Rope, Safety Cages and any Size and Forms of Cars. McCaskell's Patent Car Wheels and Axles—Best in Use.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois. New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail.

HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,750 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. BOILERS of every form, made of Pinc Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

VIGORIT POWDER.

NO ACCIDENT HAS EVER HAPPENED.

ALL POWDERS manufactured by the California Vigorit Powder Co. are SUBMITTED during the course of manufacture TO SCIENTIFIC and accurate TESTS for safety and strength.

They are teeted for Safety against Friction, Fire, a Temperature of 212° Fahr., and the varioue ehocke to which Powder is liable in practical handling.

The following qualities are common to all grades of Powder manufactured by the Company:

Safety, Non-Leakage; Freedom from Noxious Gases; Uniformity and Strength.

If consumers desire it, the EXACT STRENGTH of any Powder shipped to them will be GIVEN IN FOOT POUNDS. ☞Send for Pamphlet showing methods of testing the different qualities of all Powders.

The Company manufactures:

DETONITE.

This is an explosive involving new principles and recently patented. It is the **Strongest Powder ever placed on the Market,** in this country or abroad. It is the **Safest Strong Powder ever made.** For very refractory rock this Powder is the most economical in the market.

VIGORIT, No. 1, XX.

This Powder is **Stronger than the Highest Grades of Hercules or Giant.** It is only surpassed by "Detonite." It is suitable for hard rock.

VIGORIT, No. 1.

For general work this Powder has no superior. It has the advantage over Giant, Hercules or Vulcan in safety and freedom from noxious fumes.

VIGORIT, No. 2.

Equal to any corresponding Grade in the Market.

LOW POWDER.

VIGORIT, L. P.

This is a Powder suitable for **Bank Blasting, Log Splitting** or the work generally in which Black Powder can be used. It is STRONGER THAN BLACK POWDER, having from twice to ten times the effective strength, depending on resistance. It is **Superior to Judson Powder,** in being more sensitive to the cap and more convenient in handling.

Best Qualities of FUSE and CAPS sold at Lowest Rates.

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

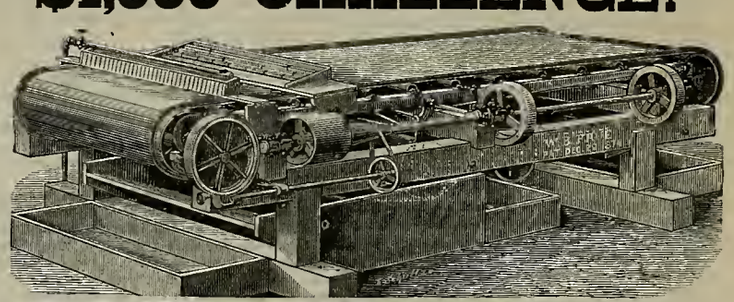
$1,000 CHALLENGE!



THE FRUE ORE CONCENTRATOR.

Nearly 300 are now in use, giving entire satisfaction. Awarded First Premium and Silver Medal at the Industrial Fair for 1880 of the Mechanics' Institute of San Francisco, Cal.

Saves from 50 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal; water required is less than in any other wet Concentrator; the power required per machine is less than one-half horse power; the labor required is light, one man on a watch can attend to sixteen machines.

We challenge any other Concentrator in use for a fair and impartial competitive trial, side by side, for stakes of $1,000 each, and we mean business.

☞A machine with all improvements can be seen in working order and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont street.

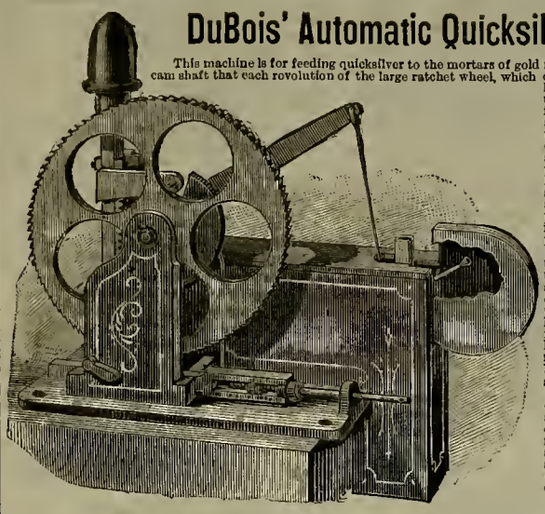
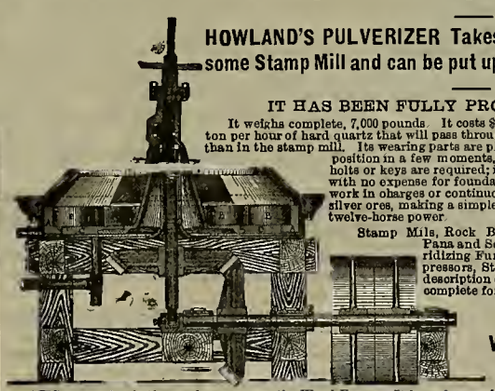
DuBois' Automatic Quicksilver Feeder.


This machine is for feeding quicksilver to the mortars of gold mills. It is so connected to the cam shaft that each revolution of the large ratchet wheel, which can be regulated to revolve once in one, two, three or four minutes, as desired, dips a small cup into a reservoir of quicksilver, and by a trip of the cam, empties the contents into a pipe leading down to the mortar, supplying an exact quantity at regular intervals, superseding the ordinary hand feeding, which is of necessity subject to great irregularity, and liable to neglect. It renders the amalgamation of all the gold in the pulp equally certain and perfect.
The mechanism to produce this depression and elevation of the cup, is driven by the cam shaft, similarly to the self-feeders, over which so much ingenuity has been expended to regulate the delivery of ore to the mortar. As it is to be desired to have the ore go in constantly and regularly, so it is equally desirable to have the mercury fed constantly and regularly.
A chief point of excellence of this machine is, that it allows the quantity of mercury which would be otherwise fed in mass, in one hour, to be subdivided into a number of small portions, and fed almost continuously; *i. e.*, from every one to four minutes.
Price, complete, $100.
For Sale by **WHITNEY & MARSHALL,** Sole Agents
22 & 24 Fremont St., San Francisco.
Dealers in Iron, Steel, Hardware and Mining Supplies, Wrought Iron Pipe and Fittings, Pump Columns, Wire Rope, etc. A large stock of Boiler, Plate and Sheet Iron of every description.

MOREY & SPERRY,
MANUFACTURERS OF
Gold and Silver Grinding and Amalgamating Machinery
HOWLAND'S PULVERIZER Takes the Place of the Cumbersome Stamp Mill and can be put up in one day ready for work.
IT HAS BEEN FULLY PROVED AND TESTED.


It weighs complete, 7,000 pounds. It costs $1,500 ready for the belt. Will crush one ton per hour of hard quartz that will pass through a 40-mesh screen. The wear is less than in the stamp mill. Its wearing parts are plain castings and can be dropped into position in a few moments, as shown by the letters A, B and C, no bolts or keys are required; it can be set upon the floor of a mill with no expense for foundations, and can be used to crush and work in charges or continuous. It will amalgamate either gold or silver ores, making a simple, cheap and effective mill, it requires twelve-horse power.
Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores, Chloridizing Furnaces, Retorts, Rock Drills, Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies. Iron Work complete for Wood Frames, also
SPERRY'S WROUGHT IRON FRAME FOR STAMP MILLS.
☞ Great saving in time and money over the Wood Frame. It is made complete with Wrought Iron Frame ready to put upon the foundation. We construct Mills with Stamps weighing from 350 to 900 pounds for Gold and Silver Ores. Wet or Dry Crushing Mortars.
MOREY & SPERRY—Warerooms, 92 and 94 Liberty St., N. Y.

LEFFEL'S IMPROVED WATER WHEEL.

PRICES REDUCED!
PATENTS REISSUED 1868.
The "OLD RELIABLE" with improvements, making it
THE MOST PERFECT TURBINE NOW IN USE.
Comprising the **Largest** and the **Smallest** Wheels, under both the **Highest** and **Lowest** head used in this country. Our new Illustrated Book sent free to those owning water power.
Those improving water power should not fail to write us for **New Prices**, before buying elsewhere. New Shops and New Machinery are provided for making this Wheel. Address
JAMES LEFFEL & CO., Springfield, Ohio, and 110 Liberty St., N. Y. City.

New Mining Horse Power.

The demand for a better Horse Power, suited to more general use, has resulted after much experience in the above machine, which we can recommend as a First-class Hoisting Power, under complete control of man tending bucket, through levers connecting with brake and clutch.
This power is light and strong, so that two or more horses can be used for crushing ore or other work.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

SIDE SADDLE.—Lewis A. Reister, Chico, Butte Co., Cal. No. 255,334. Dated March 21, 1882. The improvements on this new and improved side-saddle consist in sundry details of construction. It is constructed of leather, with plain or quilted seat. Having no side bars or cantle-board, the saddle fits directly upon the horse's back, and the rider sits low down. The advantage of this is that there is no rock from side to side, and no danger of hurting the horse's back. The rear portion of the saddle or the seat has no frame whatever, and is simply a pad which extends backward from the steel saddle-tree, and lies directly upon the horse's back. It is an objection to the old style side-saddle that it gives its rider an awkward and uncomfortable position, and many have preferred to use an ordinary blanket with stirrup and hand-hold. This new saddle gives to the rider a comfortable and graceful position, embodying all the advantages of the blanket alone, while giving a firmer and more secure seat, because of the steel tree. By having the horn low down, the right knee does not rest too high for ease, nor do the hips cramp, as they are liable to do with a curving tree of the old style.

HOSE COUPLING.—Edward A. Rix, San Francisco. No. 255,335. March 21, 1882. This invention relates to a device for securing the ends of flexible hose to couplings. It consists of a tube fitting within a section of hose, and provided with a flange, against which abuts another flange combined with a ring and clasp, provided at one end with a small screw, and at the other end with a sectional ring having fastening lugs and bolts.

The Microscope in Metallurgy.

At the last meeting of the San Francisco Microscopical Society a paper by Melville Atwood, on the above subject was read by the secretary, as follows:

In a former paper read before this society, the subject being "The Microscope in Geology," I had occasion to remark that the microscope in mining would soon become as important an instrument in guiding the miner in his operations as the compass was to the navigator, as only by the aid of the microscope could he correctly determine what was so necessary for him to know, namely, the true character of the enclosing rocks of the different metalliferous veins he was either prospecting or working, and thereby rendering mining a less hazardous undertaking, and not allowing the art to degenerate into a mere "its porphyry," or "trial-all" system. We are now only beginning to understand and realize the great value of the microscope in metallurgy.

One of its most important uses, however, and to which I particularly wish to call your attention, is in the milling of gold quartz, where it has aided us in distinguishing and proving in the most unmistakable manner the true condition of the gold in iron pyrites, which we now know to exist in a metallic state, being, therefore, only mechanically mixed with the iron pyrites, so that the amalgamation of the gold in the raw ore can be easily effected, and with little loss, if ordinary precautions are taken to have the ore reduced fine enough to liberate the gold inclosed in the finer particles of pyrites. With considerable trouble and expense I have procured samples of pyrites from most of the mining counties of this State and made a careful microscopical examination of them. For convenience and accuracy in their determination, I fastened the crystals and fragments of crystals with marine glue to glass slides. The result of my examination in every respect confirms what was arrived at by Messrs. Daintree and Latta, of Australia, who, in 1874, published the results of their discovery, and, guided by it, up to that date Mr. Latta, at the Port Phillip mines, had treated successfully about 2,400 tons of iron pyrites, which are here called sulphurets. The work has been anything but an easy one for me, but I have done it purely on economical grounds, hoping that the knowledge of the true condition of the gold in iron pyrites might assist and greatly simplify the milling of what has been called "rebellious ores." The specimens I have the pleasure of submitting for your inspection, have been selected as fair samples of what I have examined, and I hope they may prove interesting apart from their utilitarian value. A few weeks ago I addressed a letter, the subject "Milling of Gold Quartz," to the State Mining Bureau (*vide* MINING AND SCIENTIFIC PRESS, December 17, 1881), copies of which can be had by any member of this society who feels interested in the matter. I feel certain that if the suggestions contained therein are fully carried out at the different gold mills, it will add greatly to the gold returns of this State. With regard to the amalgamation of the gold in the raw ore, as far back as 1831, in a communication to the London *Quarterly Review*, on the several modes of amalgamation as practiced in the Hungarian and South American mines, mention is made of a new mill introduced in the Schwartz mines, Tyrol, by Mr. Hocheder, called the "self-acting immediate cold amalgamation mill"—immediate because the stamped ores are given over to it immediately from the stamps. Its action is grinding, washing and precipitating, after which amalgamation takes place. During that process the quicksilver so effectually extracts nearly every particle of gold, or even silver, if not mineralized, that even the most scrupulous assays will scarcely detect any trace of those metals in the residue beyond a trifling quantity in a mineralized state, and this being the same contents as those of the pyrites gained in former washings, proves completely that the present increase of gold, which is obtained from the minutest *laminæ* of gold, which the quicksilver sucks in at the first contact with them, and which are so light that they would be carried away even by the softest current of water on the 'strakes' (blanket tables), as they have no more body than a gold leaf, and very little breadth." In a number of the same *Mining Review*, but published in 1832, on the extraction of the gold by amalgamation of the raw ore, it says: "On the mode of treating auriferous pyrites in Piedmont by M. De Villeneuve, from the *Annales des Mines*. The auriferous pyrites near Venzons are combined with blende and galena, the quality of this mineral varying from eighty-five francs to less than two francs per quintal, or from .000494 to .000010 of fine gold—the number of mills in the valley cannot be less than two hundred." Then follows a long account of the description of the mills, and the account ends by saying that it takes twenty-four hours to complete the amalgamation.

Mr. Atwood's paper was illustrated with several mounted specimens. One slide showed the gold on a crystal of pyrites, which, with the aid of an inch objective, was seen as a beautiful gilding on some of the planes of cleavage. Another slide showed the gold in little drops, also filling some of the small cavities. Still another slide showed the gold in little specks imbedded in the pyrites. Another specimen disclosed the gold in fine specks or scales mixed with the sesquioxide of iron.

Mr. Atwood has found that in the examination of all metals, if possible, good bright daylight should be used. The specimens, as seen by lamplight, did not exhibit the gilding as well as it was seen in Mr. Atwood's office in the daytime. He is to pursue the subject of the use of the microscope in metallurgy at a subsequent meeting.

Lifting Jack for Stamp Mills.

Charles Gracey, of Contention, Cochise county, Arizona, has devised a lifting jack specially adapted for lifting the stamps of ore mills. It consists of a lever fitted through a slotted vertical rack and carrying eccentrically pivoted pawls, which are adapted by the motion of the lever to alternately engage with the rack on each side, and to travel upward, carrying with them said lever. The vertical rack is provided with a peculiar foot, which adapts it to fit the lip of a mortar, in which position the lever extends within the mortar through the screen opening, and may be fitted under the stamp to raise it.

In stamp mills there is frequently a necessity to raise a stamp, and hold it in a raised position. This is accomplished in various ways, but usually by placing blocks under them—a well-known device. This lifting device we are describing is ready of application and serviceable.

A standard is made in two parts, leaving an extended slot between, and upon the sides of the standard are notches having a straight top and inclined faces.

A lever passes through the central slot and has on its sides studs which slide in grooves in the standard. Pawls have their upper ends slotted, to receive the lever. One pawl is pivoted to the lever on each side of the standard, and the pivot points are so placed out of line of the center of gravity that the pawls will always swing toward the standard and engage with the notches or teeth. The ends of the pawls are so made, that in ascending they will slip over the inclined faces of the teeth and engage with their straight tops.

In applying the device, the broad, bifurcated foot rests upon the lip on the inner lower edge of the mortar. The lever, when at the bottom of the standard, projects its short end into the mortar through the screen opening, and, being about on a level with the bottom of the stamp, is fitted under said stamp, its upturned point enabling this to be done without trouble. When the end is under the stamp, the long end of the lever is drawn up and down by the operator. When the lever is pushed up the inner pawl forms a bearing, and the outer pawl is raised to a higher notch, and so on to the top. Each notch forms a new bearing for the elevation of the lever. As the lever rises, its end being under the stamp, the stamp rises also. By extending the leverage, the operation may be very easily performed. The stamp may be thus raised to and sustained in any desired position.

ANOTHER furnace is to be started at the Eureka Con. The Ruby-Dandersberg and Matamoras are likely to start soon. So, all in all, there is no reason why we should not feel more jubilant than at any time since the first discovery of a mine on Ruby hill.

THE California Iron Company expects to chop about 25,000 cords of wood in Placer county next summer, which they will convert into charcoal.

Business Offices and Sunny Rooms to Let.

We have some desirable rooms to let adjoining the offices of this paper which will be rented on favorable terms. Stair entrance, No. 252 Market St. Elevator, No. 12 Front St. Parties wishing offices, etc., will do well to call and see them. DEWEY & CO.

Canvassing Agents.

We want several canvassing agents who will make it their business to solicit subscriptions and advertising for our first-class progressive newspapers. Men of ability and experience can secure good pay and permanent employment. Send references and state your past occupation, etc., to the publishers of this paper.

Cylinder Printing Press for Sale.

A large cylinder Hoe printing press, for country newspaper work, can be bought cheap by addressing

Pleasure in Recommending, Etc.

OAKDALE, Stanislaus Co., Cal., March 6, 1882.

Messrs. Dewey & Co.—DEAR SIRS:—I hereby acknowledge receipt of patent with copies, for which please accept my sincere thanks. I shall take pleasure in recommending your agency when I have an opportunity.

Yours Truly, J. M. NELSON.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

G. W. MCGREW—Santa Clara county.
M. P. OWEN—Santa Cruz county.
B. W. CROWELL, San Benito and Monterey counties.
J. W. A. WRIGHT—Merced, Tulare and Kern counties.
JAMES C. HOAG—California.

Sewing Machines.

Several first-class styles, good as new, will be sold at a bargain. Call on or address H. F. D., at this office.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

PERSONS receiving a sample copy of the MINING AND SCIENTIFIC PRESS *with this notice marked*, are requested to examine the merits of the same, and consider fairly its claims for support, and if consistent, subscribe for the paper through the P. M. or agent delivering it, or otherwise. We shall send it, on trial, at the rate of $4 per annum for any period the reader may wish. Please notice our terms elsewhere, and if desired, send for further samples and information. Those who can circulate this No. further to our advantage are invited to do so.

BOUND VOLUMES OF THE PRESS.—We have a few sets of the back files of the MINING AND SCIENTIFIC PRESS which we will sell for $3 per (half-yearly) volume. In cloth and leather binding, $5. These volumes, complete, are scarce and valuable for future reference and library use.

CORRESPONDENCE on mining and other subjects represented by this journal is solicited from all reliable sources. Send us information, early and often, if ever so brief.

THE State Mining Bureau, No. 212 Sutter street, is open to the public from 10 o'clock A. M., to 5 o'clock P. M daily, (Sundays excepted). Henry G. Hanks, State Mineralogist.

A TURNED LEAF will point out the article supposed to be of special interest to persons receiving sample copies of this paper.

ANNUAL STATISTICIAN of 1882.—"It is the most complete and accurate work of its kind in the world."—*S. F. Call.* Address L. P. McCarty, 502 Taylor st. Price, $4.

Mining and Other Companies.

Persons interested in incorporations will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for advertising.

Bullion Mining Company.—Location of

Principal place of business, San Francisco, California. Location of works, Gold Hill Mining District, Storey county, Nevada.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 29th day of March, 1882, an assessment (No. 23) of Thirty (30c) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, Room 3, Safe Deposit Building, 328 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the second (2d) day of May, 1882, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Wednesday, the twenty-fourth (24th) day of May, 1882, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

J. M. BRAZELL, Secretary.

Office—Room 3, Safe Deposit Building, No. 328 Montgomery street, San Francisco, Cal.

Mechanics Mills, corner Mission and Fremont street.

Scientific, Mining and Other Valuable Books.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS Office, S. F.

BY GUIDO KUSTEL.
MINING ENGINEER AND METALLURGIST.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequaled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery etc., which alone are of the greatest value. PRICE, $7.50

ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver. 1880.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 156 pages, embracing illustrations of furnaces, suplements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.

Price, $3.00 coin, postage free.

Carson and Colorado Railroad.
(NARROW-GAUGE.)

The Company announces the completion of its line March 1, 1882, to CANDELARIA, Columbus Mining District, Esmeralda Co., Nev., 158 miles from Mound House (Junction with Virginia and Truckee Railroad).

STAGE CONNECTIONS,

At Hawthorne with U. S. Stage Company's daily coaches for Aurora (26 m.); Bodie (37 m.); Lundy and Bridgeport.

At Luning (125 miles from Mound House) with Gilmer, Salisbury & Co.'s tri-weekly stages (leaving Tuesday, Thursday and Saturday mornings) for Grantsville, Belmont and Tybo.

At Belleville (150 miles from Mound House) with Belleville and Independence Stage Co.'s stages for Benton (40 m.), Bishop Creek, Big Pine and Independence.

At Candelaria, with U. S. Stage Co.'s stages for Columbus (8 m.), Silver Peak, Montezuma, Alida Valley, Gold Mountain, etc.

THROUGH TICKETS

To the above points for sale at San Francisco, Sacramento Reno, Carson and Virginia R. R. Ticket offices

This is the direct and natural route for Passengers and Freight, to points in Southern Nevada, Mono and Inyo counties, California. The line, laid with steel rails and redwood ties and equipped with new and first-class rolling stock, is penetrating new and most promising Mining Districts which are now attracting deserved attention throughout the country.

For information on through freight rates apply to
H. M. YERINGTON, Gen'l Supt. D. A. BENDER, Gen'l Freight & Pass. Agent.
Carson, Nev.

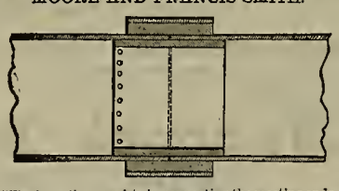
NEW TREATMENT BY INHALATION, for Consumption, Asthma, Catarrh, Bronchitis, Dyspepsia, Debility, Rheumatism, Neuralgia, and all Chronic Headache, Nervous Disorders. Prepared by DRS. STARKEY & PALEN, Philadelphia, Pa. Package contains all directions, and is easily sent by express, ready for USE AT HOME. H. E. MATHEWS, Forwarding Agent, 606 Montgomery street, San Francisco, Cal. Send for Free Pamphlets.

JOINT FOR SHEET METAL PIPE.
RE-ISSUE PATENT NO. 8,214 TO JOSEPH MOORE AND FRANCIS SMITH.



"The invention consists in connecting the meeting ends of the pipes firmly together and placing a band or tube around the outside of the meeting ends, which is larger in diameter than the pipes, and which is long enough to extend a distance on each side of the joint and then filling the space between the outside band or tube and the pipe, with a packing of lead or other soft material, either by casting or tamping."—(Extract from specification of Patent).
These joints have been tested for 8 years, and are undoubtedly the best joint made for sheet-iron pipes—THE BEST AND CHEAPEST.
ANY INFRINGEMENT WILL BE PROSECUTED.
FRANCIS SMITH & CO.,
Manufacturere of Pipe of all Kinds.
130 BEALE ST., SAN FRANCISCO.

Rare Cabinet of Minerals.
A physician who has long resided in the mines and other parts of California, and gathered a large and valuable collection of minerals and other specimens, offers the same for sale at a bargain. Address "Cabinet," box 2361, San Francisco.

E. MAIN, 315 Folsom Street,
Makes to order Gents' Fine French Calf Boots from $6 to $10; Gaiters from $3 to $6; Alexis from $3.50 to $5; Mens' Heavy Kip Boots, $6; Oxford Ties, French Calf, $4; California Leather, $3.50; Men's Working Shoes from $2.50 to $3; Children's Shoes made to order. Persons in the country ordering to the amount of $12, I pay the express charges. I sell nothing but my own manufacture.

This paper is printed with Ink furnished by Chas. Eneu Johnson & Co., 509 South 10th St., Philadelphia, and 59 Gold St., N. Y. Agent for Pacific Coast—Joseph H. Dorety, 527 Commercial St., S. F.

Patent Agency.

[ESTABLISHED 1860.]

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 252 Market St., S. F.

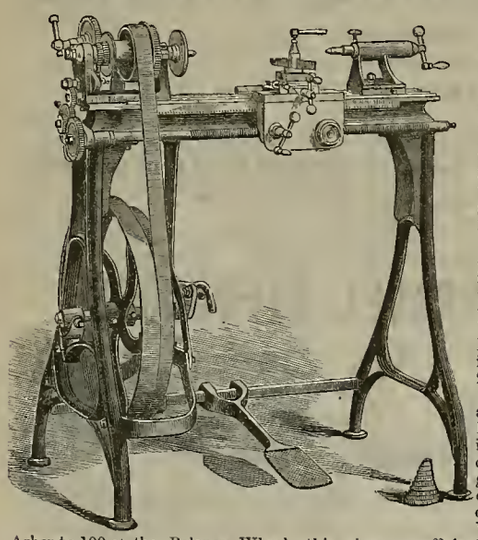
SCREW CUTTING LATHE.



This cut represents a new screw cutting Foot Lathe which was put on the market about two years ago to meet the demand for a first-class tool at a low price, which will do a great variety of work, both in metal and wood, and is the best Lathe made, considering its capacity and price. The cut gives a good idea of its appearance, and below we give dimensions of parts and general description.

Description of Lathe, 4 ft. Bed.

The Lathe occupies a floor space of 28 by 48 inches, the centers being 44 inches high from the floor; the bed is 48 inches long, 6½ inches wide, 5½ inches deep, with double Vs. for Carriage and Tail Stock. It swings 10 inches over bed and 6 inches over carriage, and will turn 26 inches long.

The Head Stock is back geared, and the Cone has three speeds for 1¼ inch belt, the smaller being 3 inches diameter, the larger 6 inches diameter; this, with the back gears gives six different speeds, the fastest giving about 1,000 revolutions of the Arbor to 100 of the Balance Wheel; and the slowest, 75 of the Arbor to 100 of the Balance Wheel; this gives a sufficient range for all kinds of work.

The Arbor in Head Stock has a ⅝ inch hole through it, which is very convenient for turning the ends of long rods, making small screws, studs, &c. The Centres are ½ inch diameter. There is an attachment in Head Stock for reversing the motion of Carriage.

The carriage has a rack and pinion for moving it by hand, and a split nut moved by a cam on the face of Carriage to throw it in gear with screw; the reversing motion is in Head Stock.

The Tool Post has a slot for tools ⅝x1¼ inches; the tool is adjusted by a wedge made on the arc of a circle and fitted to a convex washer. The leading screw runs the whole length of Lathe, and has 10 threads to the inch. A set of gears go with the lathe which will cut all common threads and a great variety of other sizes by compounding them; there is a screw stop on the Carriage for screw cutting, &c.

The Tail Stock can be set over for turning tapers, &c. The spindle of Tail Stock is 1 1-16 inches diameter, and has a motion of 3 inches. The center is fitted to a taper hole, which is the method adopted by all the best makers, and is the same size as the one in Head Stock, so that chucks and other tools fitted to one can be used in the other.

The Foot Motion, we consider the best made, the crank is adjustable and the shaft has swivel bearings; the balance wheel is 22 inches diameter and has 3 speeds to match Cone on Head Stock.

Send for Circular on Lathes.

SAN FRANCISCO, SATURDAY, APRIL 8, 1882.

VOLUME XLIV Number 14.

New Dry Ore Separator.

Wm. O. Bonrne, of New York, bas invented an ore concentrator of that class in which vertical puffs of air through a working perforated plate accomplisb the object. The invention is intended as an improvement on another machine, the main object heing to simplify the oonstrnction hy dispensing with the cranks and their shafts over the belts, and to this end the invention oonsists of a separating chamber and hellows directly connected together hy arms, as sbown in the engraving.

The frame work is represented hy *a*, with its base-rail *b* and top rail, *c*, supporting a top, *d*, which carries the separator case or ohamber A, provided at its lower end with an air-chamher, *e*, resting npon friction-rollers *h h*, secured npon the top plate, *d*, and which hear against supporting-rails, *s*, secured nnder the hottom of the separator case or chamher A, and npon which it is moved to and fro in working the machine. *f'* shows the perforated plate, and *f'' f'''* represent the woven-fahric surface-cushion forming the hottom of the receptacle B, and stitched together, forming a hed for the pulverized ores, which flow automatically from the hopper *l*. *k* is an inclined spont at the opposite end for escape of the waste material. *t* is a curl around the ore-bed. These several parts are readily separated by loosening the hooks *u u*. Below this separator-box, and within the supporting frame-work, a donhle-acting, vertioal hellows, C, having sides *c' c''*, is seoured, the valves of which oscillate upon the hase-rail *b* and have inlet air-valves *m n*, with air-outlets by pipes *o p*, which are connected by flexihle or jointed tuhes *t'* with the lower ends of pipes *v*, attached to the lower face of the separating-chamher, so as to register with the orifices *u* therein, capped by out-let valves *r*. Upon the top edges of the oscillating sides *c' c''* of the hellows C thin plates *g* are secured, which pass into forks in the ends of snspended plates *v v*, fastened on the under side of the frame of the separator-hox.

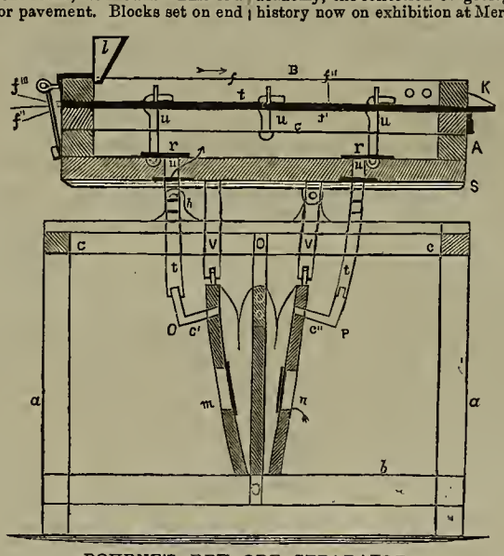
The operation of the apparatns is as follows: The hopper *l* heing charged with the pulverized ore, it will fall upon that end of the separator-bed. The hox is then pushed endwise hy hand or other power, and it will move along the rails hy the carrying-wheels *h*, which motion will cause the mineral to spread on tbe surface of the hed. At the same time the bellows *c'* will collapse, forcing its air, hy the pipe *o* into the air-chest and through the sieve and bed of ore. The motion is then reversed, when *c'* will take air hy the valve *m*, and the hellows *c''* will give ont its air to the chest hy the pipe *p*, which operations are repeated at will. The action of the air will lift and agitate the powdered ores, oausing the heavier or metalliferoue portion to concentrate npon the surface of the hed, and the lighter or waete portion romaining at the top will gradnally work toward and finally flow out hy the epout *k* as "tailings," and when the mineral has collected on the hed in quantity to embarrass working the machine, the material may he collected hy a brusb and shovel for removal.

WHITE AND CHINESE MINERS.—Tbree years ago, eays the Grass Valley *Union*, there were 75 Chinamen and 25 white men employed at the Milton mine, French Corral. Now the entire force consists of white men. A eimilar revolntion has heen hronght about in all the large mining properties on the ridge, through the anti-Chinese agitation, and the exertion of the local Miners' Unions. All the white minere are now memhers of these Unions, as well as all the hossee and foremen. There are some Chinese yet employed in a few mines owned hy white companies, hut it has become so nnpoonlar to employ this labor, that it will not he long before it can he said that there are no Chinese employed hy white men to work in the mines of Nevada connty.

PACHECO tried to pass the hill Saturday donating certain military lands in Inyo Co., Cal., known as Camp Independence, for school pnrpoees, hnt failed. He gave notice, however, that he would try it again next week.

Sluice Pavement.

In answer to the inquiry as to the hest material for paving sluices, where a great deal of material passes over them, we give an engraving showing a rock-paved sluice. The rocks are placed as shown on the hottom of the sluice, with hraces at intervals to keep them firmly in place. A thick streak of plank is placed along the sides above the rocks, as shown. This is a common lining or pavement. Blocks set on end



BOURNE'S DRY ORE SEPARATOR.

are more common. Old railroad iron is also used, as are broken car-wheels; the irregular crevices making good riffles. Almost anything will do that will stand wear and form suitable crevices, but blocks and stones are most common.

A SEVERE MINING ACCIDENT.—Yesterday morning about 6:30 o'clock Philip Dolan met with a sevsre accident and had a very narrow escape from death. The accident occnrred at the joint Ophir and California winze, which was sunk to the 2900 level. It is a two compartment winze, and Dolan stooped down over that compartment in which the cage was np. While in this position he called out to the men below to send up the cage, meaning that of the other compartment, which was down. At this moment the cage that was above came down and struck him on the head, jamming him down to the floor and holding him prisoner hy the head until the cage was rung up. The bridge of his nose was broken and his face and head badly bruised. He was taken to his residence on Summit street, and will come ont all right in due time. But that the cage was a light one, such as is used in winzes, and traveling slowly, Mr. Dolan would undouhtedly have heen decapitated.—*Virginia Enterprise.*

PAVEMENT FOR MINING SLUICES.

COPPER mines are what miners are now striving for. They are preferred to gold or silver properties. New Mexico will produce some splendid minee of this character.

BONANZA CITY, N. M., will, the minere think, grow rapidly during the approaching eummer. It hae waited for its hoom for several years, and it hegine to look as if the time had come.

A Generous Gift to Science.

Tbe following report, read at the last meeting of the California Academy of Sciences, is self-explanatory: On tbe 20th of March, 1882, the joint committee of the trustees of the Academy of Sciences, appointed Geo. Davidson, Justin P. Moore and H. W. Harkness a special committee (with power to add to their number) to obtain subscriptions to purchase, for the academy, the collection of geology and natnral history now on exhibition at Meroantile Library hall. The committee examined tbe report made hy the previous committee appointed hy the council and trustees to devise some systematic plan of action; and after an nnderstanding with Mr. Ward, the committee was in a position to know definitely the lowest price of the collection. This was due to those who were to be solicited to subscribe. The individual memhers of the committee had asked the advice and assistance of one of our life members, and were assured of his hearty co-operation. They also consulted with Charles Crocker, who had already acted so munificently that they expected mainly to profit hy his advice and influence. Upon his invitation the committee met him npon the subject and very soon learned that he had formed a definite project in his own mind to secure for the academy the whole collection as it stands.

Mr. Crocker's project was simple and to the point; he proposed that he and Gov. Stanford should purohase the entire collection and present it to this Academy. When Gov. Stanford came in Mr. Crocker named the proposition to him, and after a short interchange of views as to the merits and wante of other institutions, Gov. Stanford promptly and cheerfnlly acceded to the project. Each of them drew his check for the sum of $8,000; and thus, through the broad spirit and generosity of these two gentlemen, the California Academy of Sciencee becomes the possessor of this magnificent collection, which mnst necessarily grow hy additions, and thus become the largest museum of geology, mineralogy and natnral history on the Pacific coast. The committee then proposed to the donors that the collection should hear their names, and after overcoming objectione on their part, we are permitted to use our judgment in this matter. This committee therefore proposes that this collection shall he known as the "Crocker-Stanford Collection of Geology, Mineralogy and Natnral History." As the subject-matter of education was freely discnssed at this interview, the committee feel they may he justified in availing themselves of the opportunity to place npon record their high appreciation of the liberal and advanced sentiments which these gentlemen expressed upon the snbject of such collections, as great factors in the practical education of our youth, of their deep interest in technical edncation generally, and especially of their conviotious that the University of California wonld attain the highest possihle position as the culminating point of the educational system of this State and coast.

The committee also heg to report that Messrs. Crocker and Stanford were assured this collection would he continned on exhibition nnder certain conditions. In view of this fact, your committee have to-day taken steps to secure snbscriptions to pay the rent and cost of exhibition, insurance, etc., for the next year, in some snitable hall. Thus far we have met with favorable success, and feel that we may say that, with little difficulty, the reqnisite amonnt will he secured.

(Signed) GEORGE DAVIDSON,
JUSTIN P. MOORE,
H. W. HARKNESS,
GEORGE E. GRAY,
JOHN F. BOYD.

The committee were instructed by the Academy to solicit subscriptions to an amount sufficient to defray the expenses of keeping it open for at least a year, or until the Academy may he able to have a building of its own built, suitable as its repository.

Mr. Curry moved that suitable thanks be conveyed by the Academy to Messrs. Crocker and Stanford for their most generous donation, likely to prove so nseful to the Academy and to all students of natural science on this coast, and that the same, when prepared, he spread npon the minutes.

Mr. Moore thought the acqnisition of this collection wonld give the Academy an impulse which would eventually result in their getting a new building of their own.

Professor E. T. Cox said the fact of this donation would he an encouragement for the American Association for the Advancement of Science to accept an invitation extended them to meet here in 1883, when the presence here of its 400 memhers, all learned and celebrated scientists from all parts of America, wonld result in great good to our State, and could not fail to awaken increased interest in scientific pursuits. It would speed that momentnm which the Academy had already received through the munificent gifts of Messrs. Crocker and Standford.

NEW MONTANA MINES.—A dispatch from Chicago says: Two very promising gold and silver mines have heen discovered on the line of the Northern Pacific railroad in Montana, and rapid stridee are now heing made toward their development. One is called the Maginnis mine, and is located 60 miles south of the Missouri river, 140 miles north of the Yellowstone, 20 miles west of the Mnssel Shell, and on the eastern hase of the Big Snowy mountain. The other mine, called the Clark's Fork, is located farther to the eouth. It is just west of the Clark's Fork river, south of the Yellowstone river, and very nearly touches the northern houndary of the National Park. It ie abont 60 miles southwest of Coulsen.

FREE PUBLIC LIBRARY.—The regular monthly meeting of the Trustees of the Public Library was held thie week. Secretary Moulder reported expensee for March aggregating $2,585 98. For hooke the sum of $983.02 was expended; for salaries, $944.75. The halance to the credit of the fund is $16,765.87. Accrued and estimated liabilitiee reach $9,977.31. Mr. Perkins, librarian, reported 37,903 visitore for March. During the month 18,723 hooke were taken from the library, and 12,110 used in the rooms. The Tustees authorized the purchase, at a cost of $580, of a series of photographe from the collections of the British Mnseum. George H. Rodgers was elected President of the Board of Trustees for the eneuing year.

CORRESPONDENCE.

e admit, unendorsed, opinions of correspondents.—Eds.

Snow Perils of the Upper Sierras.

A Week of Suspense in the Snow-Blocked Mining Town of Lundy.

Editors Press:—The village is situated in Mill Creek canyon, surrounded on all sides, except the east and a emall opening to the west, by precipitons mountaine of granite, rising at an angle of 50° to 70° to the hight of 2,000 to 3,000 ft. The site of the town is a gentle declivity towards the south, covering about 250 acres. On the north the mountains are fully 2,000 ft. high, and at a distance of 200 or 300 ft. from Main street they rise at an angle of 50°. On the south side Mt. Gilcrest towers to the hight of 3,100 ft. above the town, at an angle of 50°, the base terminating at Mill creek in the south margin of the town, about one-fourth mile from Main etreet, with only a few bnildings along its base. On the southwest side frowns Mt. Scowden from a hight of 2,300 ft., its upper half nearly perpendicular and its lower half at an angle of 60°. The storm began on Thnrsday night, 9th of March; on that night and the following Friday snow fell to the depth of 15 inches. Saturday was clear, but on Sunday the snow fell lightly all day, and on that night the terrible storm began in earnest and raged almost continuously until Friday, the 17th, on which day the sun rose clear and bright, and the etorm was again renewed on Saturday and Sunday, accompanied by a terrific gale, probably bringing the greater part of the snow that lodged in the canyon from the high peaks in the vicinity. By Wednesday evening (the 15th) the village was snow-blocked and all commnnication with the outside cut off. The Sierra telegraph line kept up till about 5 P. M. At that hour came the

First Alarm from an Avalauche.

Starting near the summit of Mt. Scowden, ite velocity was something fearfnl and indescribable. Dropping from tbe almost perpendicular face of the mountain, at a hight of 2,000 ft. above the town, it came with such tremendous force, causing it to leave the ground long before reaching the hase, shooting with lightning speed as far east as Chicago avenue, 1,500 ft. from the base of the mountain. The first nnfortunate people residing in its track were the family of Mr. Mayes, consisting of himself, wife and three children. The house (a frail one) was swept away, and the entire family covered four ft. deep. It next strnck the large canvas house on the north side of Chicago avenue, occnpied by Mr. Winter and wife. Tbis was completely demolished, and both occupante buried to tbe depth of eix ft. Fortnnately none of the seven persons in these buildings were seriously injnred, as they were quickly uncovered hy a number of citizens going to tbeir assistance. Before striking these houses the avalanche shot entirely over a cabin occupied at the time by Jos. Carron, Gns Duval, George Cbagnon and one other man. It was buried by snow falling on it, but none of the men were harmed. The track of thie avalanche was a little east of the May Lundy mill, harely missing it, if, indeed, ite force was not high enongh in the air to have cleared the roof of the mill altogether. An hour later the next

Avalanche Came from the North Side,

Directly back of the most densely built portion of Main street. Its force was broken by striking on a level hench or bluff 200 feet back from Main street, almost overhanging the May Lundy botel. The whole mass of the slide seemed to be instantly dashed into spray, and dispersed in every direction, doing no damage beyond filling the center of town with flying snow, and blinding for the time those in the streets, and plastering the house-fronts on the opposite side with the hardened snow. Although there had been no damage from this, it was terrifying enough to thoronghly alarm every person in the town. It bad become quite dark by that time, and the storm was raging with a fury to appal the bravest. No one knew where to look for safety. It soon became evident that this part of the town was comparatively safe, and many women and children in exposed locations collected there, and the citizens who had no familiee to protect, collected at several points of rendezvous, prenared with shovele to go at tbe first call of alarm, and it is fortunate that they did so. Avalanches were now coming from all sides. Every few moments through the blinding storm came the roar of the rocket slide, followed by a rush of wind and flying spray, and occasionally the crashing and thundering of the heavier avalanche, that kept closer to the ground, striking terror to the stoutest hearts, though they may have felt safe themselves. This Wednesday night was one that will never be forgotten by the inhabitants of Lundy, and the poor fellows on tbe outside in isolated buildings, far

Beyond Help from the Town

At 11:30 came faint cries for help through the roaring of the storm; they seemed to come from the base of Mt. Gilcrest, neerly one quarter of a mile south of Main St. It was aoon found by a large party of rescuers that an avalanche had swept down from that monntain, crossed Mill oreek, and carried away the log cabin occupied that night by Abner and J. A. Bagby, and Fulton Ishell, and buried all of them deeply. By good fortnne, one of the brothere could work a little, and by great effort managed to dig near enongh to the surface to meke himself heard. Tbe two Bagby brothers were soon releesed, but it was an hour before Isbell was rescued. He was held down firmly by the logs of the building, and could not have survived much longer. Their escape was almoet miraculons, as the honse (a very etrong one) was entirely demolished, with everything in it. Another terrific avalanche came just as the rescners approached the Bagby house. The spray from it blinded and etaggered the party, thongh it came nearly a half mile west of them.

It Shot Down from Mount Scowden,

Taking in its course the May Lundy mill, at the west end of Cbicago avenue. It seemed to have shot entirely over the mill, only crushing in the back wall of the blanket and pan rooms, and carrying away the emokestack, jumping the mill and landing tons of snow in the dump yard beyond, end rushing as far as the store, 200 feet further east. On the eonth side of Mill creek, in the rear of the mill, this avalanche swept away a small house, occupied up to that evening by two men, who just escaped in time. All through the night came the rush of the slides and the roar of the heavy avalanches, which conld not be located by the watchers. No further destruction occurred within tbe town limits, and the light of morning was welcomed by many anxious watchers, while on the outside it was far more disastrous. At 11 o'clock,

The Most Terrible of All the Avalanchee

Descended into Lake canyon, two and a half miles south of town. It started near the summit of Mount Discovery, over the north end of the Jackson mine and sonth end of the May Lundy mine, breaking along the face of tbe mountain for several hundred feet in width, narrowing again as it descended, gaining force end velocity, and running one and a half milee before stopping. Situated in the center of Lake canyon, on a considerable knoll, was the two-story frame bnilding owned and occupied by Trumble & Monroe, and occupied on that fatal night hy Stephen and Robert L. Trumble, Henry Sboemaker, Alex. McKean, Conrad Hoblitzel and D. B. Grant. The house was etruck and crushed into fragments, and carried 100 feet on to higher ground. All of tbe sleeping occupants were buried deeply. Stephen Trumble, however, dng his way out, and reached tbe cabin of Patrick Ragan, barefooted and nearly naked, through the terrible etorm. He was only enahled to do this by fortunately getting hold of two blankets that were cast near him in the wreck. These he threw out before him, and crawled to the vicinity of the cabin, as near as he could guess at it in the storm. He was pretty hadly hurt, and also frozen, but at present is able to be ahout. Mr. Ragan, the only person in the vicinity, went to the wreck and searcbed till daylight; tben, feeling snre that there could be no chance for any of the others to he still living, he came to town for assistance. He arrived at noon, and ten men

Volunteered to Go Up,

Hoping to find some of them living; tbe constantly threatening avalanches from the nearly perpendicular walle of Lake canyon, rendered their efforts almost hopeless; they, however, reached the scene of the disaster on snow-shoes by 5 o'clock, and eoon released Hoblitzell alive; he had just recovered consciousness and made himself heard. He had been buried for 19 hours, six feet deep under the snow, and his snfferings were horrible; by six P. M. they had recovered the deed bodies of Roht. Trumble, Shoemaker, and McKean, bnried abont eight feet deep and apparently killed or smothered at the first. Darkness closed in and prevented further search for Grant, and fortnnately so, for a second avalanche came shortly after, larger than the one of the previous night, burying tbe recovered bodies 16 feet deep, and fnrther work had to he euspended until the following Monday, the 20th, when 22 men went up and excavated the three bodies a second time, and fonnd that of Grant, who had been killed outright in the first avalanche and carried 100 feet to near the place where S. E. Trumble had extricated himself. Other slides occurred in Lake canyon, one sweeping away the stahle at the toll-house. Friday morning wae cleer and bright, and hy 4 P. M., H. P. Medlecott, Joe. Plant, Jas. McCollum, and William Miller came into town from the Gorrilla mine, one mile up Mill creek; their escape from death was almost a miracle. The house was situated under a perpendicular bluff 200 feet high. On either side of the bluff was a eharp canyon reaching to the snmmit, down which thundered avalanches at short intervals all through the early part of Wednesday night, nntil the canyons on either side were piled with snow to a great depth. At abont midnight a slide broke off laterally from the west canyon and crushed the house, burying them all 10 feet deep. Fortnnately one of them was in a position to work a little and

By Great Labor Dug to the Surface,

And after houre of labor released another. Judge Medlecott and Plant were in the wreck four hours; the former nnder the weight of 10 ft. of enow, with the hsavy hoards of a sleeping hnnk pressing so heavily on him that he could not move a limh. His sufferings were fearful, and he could not have lived much longer. Their severest trials were to come yet. All in bare feet and only their underclothing, they nearly perished before all were dug out. The storm was raging fnriously, and nothing to ehelter them. Added to this, slides were thundering past end over them; and their only chance to live now was to drift through the snow a long distance to the mouth of the tunnel, at which the blacksmith shop was situated, and both were hnried deeply out of eight, and their locality guesswork. This they

Succeeded in Reaching by Daylight,

And were obliged to remain all of Thureday and Thnrsday night without either fire or dry clothing. On Friday they started down to the town, Medlecott harely able to drag along with the assistance of the others. An hour later newe came of the destrnction of the bnildings at the Great Sierra tunnel, Tioga district, eight milee sonth of Lundy. Twenty-two men were buried in the wreck, but all were dug out with no serious injury to any. The immense avalanche that swept over these buildings came about 11 o'clock on Wednesday night, at almost the same hour as the other disasters. It was vaster in volume than any of the others, and coursed for fully two miles. The house was very strongly conetructed of logs and benked up high with enow, and the avalanche only carried away the top logs and roof, to which circumstance, many, if not all of the occupants owe their lives. By this time, all on the outside in exposed localities had been heard from except a party of four, who were living near the

Head of Mill Creek Canyon,

Three miles west of Lundy. A party etarted to their rescue on Saturday, and met two of them just ahove Wasson, on their way down. It eeeme that these men had been in a secure place, as the avalanchee that swept past and over them were spent and turned aside by a projecting cliff of rocks above the house. They report the situation in Upper Mill Creek canyon as one of almost uninterrupted avalanches from both sides. The town site of Wasson is, for the greater part, deeply buried by elides coming from both sides, the avalanches in some instances meeting midway of the canyon. Some of the buildings were destroyed, but very fortunately none of them were occupied thie winter. During these

Daye of Anxiety,

Tbe inhabitants of Lundy witnessed some sights of awful grandenr from the town. Friday morning hroke bright and oold, and there wes joy in every household. Mount Gilcrest rises abruptly from the south shore of Lake Lundy, and the town ie at the west end. On that morning a euccession of tremendous avalanches shot out from its very summit, 3,000 feet above the lake, keeping close to the mountain for several hundred feet, bnt long before reaching the base it left the ground, shooting with lightning velocity far out over the ice, and gliding across to the north shore. The writer witnessed some of the grandest of these from the very moment of starting. From the highest peak on the north face of Mount Gilcrest they shot down with tremendons velocity for a second or two. Then, as they receded from the peak sending up vast clonds of flying snow spray, white and flame-lit in the morning sun, leaping, curling, rolling higher and higher as they neared the bottom, until midway over the lake they eeemed 500 ft. high, and continued to roll far up the mountain on the opposite sbore, two miles from the starting-point. All thoughts of the danger of the pest 48 hours vanished in the awful sublimity of these scenes, witnessed as they were from a point of safety, with the glad sunlight flooding the tips of the mountaine once more.

The lesson from the

Experience of thie Unprecedented Storm

Will he of great good to the residents and mine ownere of Homer district. All places of danger are mapped ont in the memory of many who were here to see it. The impression may go ahroad, from some accounts of it, that there is no safety here; hnt snch is not the case. There is ample room in closc proximity to the minee where it is absolutely safe to build, and at every mine safe localities can he selected for their works; and with proper precantion in building in the fnture, a re-occurrence of these diaastere will never be known to Homer district again. H.

Alpine County Mines.

Editors Press:—It has been storming here the past few days and enow ie now four feet deep on a level. Of conrse all ontside work is suspended. The Alpine Hydraulic Mining Co., in which I am interested, is now running a ditch to their gronnd. It will be three miles in length and capable of carrying 400 miners' inches of water. We expect to complete it by the 1st of June and he ready for work with the hydraulic. Tbe company has 160 acres of ground; it ie prospected by three shafts and one tnnnel, and all the gronnd exposed by the same will average $1 to the square yard. We expect the first month's rnn will reimbnrse ns for the ontlay. Abont the only other mining going on at present in this district is at Monitor, where the Stella mine employs a few men and is taking ont about three tons of ore daily from the npper levels. This mine would probably, if sinking were commenced, develop some good milling ore, that would pay expenses of extracting and perhaps a snrplus for the stockholders. Jas. Curtain.
Markleville, Alpine Co., Cal.

Antimony Mine.

Editors Press:—We wish to call attention to what we consider a valnable antimony mine, located in Relief district, Humboldt county, Nevada. Thie mine is east from Lovelock, on the C. P. R. R., 18 miles, a good natural road leading to the same. The mine has been prospected a distance of 300 ft., opened in half a dozen places and a shaft sunk on one side of same 25 ft. The ledge proper is from 25 ft. to 30 ft. wide and assays from 20% to 70%. Prof. Blake visited the same and pronounced it the largest ledge of the kind on the coast. Water on the ground and thousands of cords of wood from 12 to 15 miles distant. One carload was recently shipped from same, hut the owners not being mining men or troubled witb much money, would prefer to have some one purchase and work the same successfully, as we feel confident can be done. We will take any one to tbe mine free of expense from the railroad and back, and guarantee the ledge to be as wide as stated. Emmons Young.
Lovelock, Humboldt Co., Nev.

A Blind Miner's Belief.

H. Clendenniug, tbe blind miner of Randolph Flet, this county, is a character out of the ordinary run of mankind. He is far advanced in age, and lives with his wife and 20-year-old son on a little ranch. They have some chickens and a few head of live etock, and these, together with the earnings of the hoy, who at times works for companies in the vicinity, enables them to subsist comfortably. Clendenning lost his eyesight 25 years ago hy a premature hlast when he was working at Iowa hill, Placer county. He is a man of marked intelligence and is well posted on current events here and elsewhere. His distinctive characteristic is that he believes be can locate and measure subterranean gold-bearing gravel deposits hy eurface indications. Tbe old man has a claim at Alta hill that he has worked on for 10 years, running from 4,000 to 5,000 ft. of tunnels and drifts and not as yet discovering a solitary speck of gold as hig as a pin-head. He claims, however, that tbe signs tell him in unmistakable language, that there are gold deposits in his ground, one of $500,000, another of $300,000, and a third of $200,000. The faith that ie in him growe stronger and stronger ae age creepe upon him, and the fact tbat he has fooled away 10 yeare and not realized bis dream, has no effect in convincing him that his tbeories are not founded on a practical basis.—*Nevada Transcript.*

Arizona Hydraulic.—A clean-up at the Excelsior Hydraulic digging on lower Lynx creek, eight miles east of Prescott, on Monday, (the first made this season), yielded 70 odd ounces of gold, worth $18 per ounce, paying $10 per day to the man for the work expended on tbe claim after the water came. B. C. Smith, the superintendent, says there is no end of the same kind of ground to wash, and every prospect of a long and prosperous season. H. A. Bigelow and others took out the water on the ground in question in the spring of 1806, at a cost of $4,400 gold coin, and the property has changed hands severel times since, the ditch bas been enlarged, reservoir constructed, and other improvemente made, and now, after having been worked more or less, according to tbe run of water in the spring, for 16 years, the valne of the claims is just beginning to he appreciated.—*Arizona Democrat.*

Blast Furnaces.—There were 25 blast furnaces built in the United States in 1881, and 23 were in process of erection, while 12 were abandoned. Tbe total number of furnaces existing at the close of 1881 was 716, compared with 701 at the close of 1880. At the first-named period 457 were in blast and 259 ont; at the last-named period 446 were in blast and 255 out. The total production of pig-iron in 1881 wae 4,641,564 net tons, against 4,259,414 tone in 1880, and 3,070,875 in 1879. The stocke of pig-iron unsold in the hands of makers or their agente at the close of the last three years were as follows: 1881, 210,896 net tons; 1880, 456,658 tons; 1879, 141,674.

On the Action of Salt Upon Copper.—Writing to the *Chemical News*, Mr. R. Monger, of the Middle Bank Copper works, Eogland, states that he noticed in the course of some laboratory experiments that, when melting copper and salt together, the metal became tougher. He concluded that the salt might possibly dissolve the cnprous oxide out of the copper, and proved by trial that salt has the eame effect as poling. He believes that the determination of the loss after the treatment with salt is an easy and rapid method for the estimation of cnprous oxide in copper.

It is believed in Germany that emigration to America this year will be far greater than it was in 1881. Perhaps the German government may seek to prevent such increase. It ie a matter of moment to that government that it should every year lose so many of the best and bravest of its subjects. Just now such men are much needed, as it is threatened with a Russian war. Russians do not emigrate.

Mechanical Progress.

Lubrication.

[Abstract of a note on "Lubrication," by Thomas Farmer, F. C. S., read before the Liverpool Association of Science and Arts.]

In a steam engine, where many parts are moving, a large amount of friction is produced, which tends to stop those parts, and it would ultimately do it, were they not continually re-supplied with fresh motion obtained by the burning of fuel. Hence it is apparent to everyone, that the engine has not only to overcome the resistance of the work to be done, but also the resistance offered by its own parts. In other words, the amount of heat manifested in friction is the amount of extra heat that will have to be generated under the boiler, and the extra cost of working will be the cost of the fuel necessary to produce the heat.

Importance of a Good Lubricant.

From the experiments of Morin, we find that the friction of a cast-iron shaft upon a dry bell-metal bearing amounts to 0.2 of the transmitted power, while with a wrought-iron shaft the friction is more than 0.25; therefore, if such shafts were dry and unlubricated, one-fifth and one-fourth respectively of the total fuel cost would be wasted in overcoming friction. By careful lubrication of the same shafts, the loss may be reduced to 0.065 in the one case, and 0.089 in the other. Hence the importance of a good lubricant. One of the next essential points is that it shall be properly distributed over the surface on which it is required—that just sufficient shall be used and all waste avoided; otherwise, what would have to be spent in overcoming friction will have to be spent in buying oil. Putting aside the commoner characteristics of a good oil, such as the absence of acidity, either natural or artificial, and the absence of gumminess, one of the most commonly believed ideas is, that an oil of high specific gravity is the best for lubricating purposes. Although this may be true in certain cases, yet from observations and experiments made over a long period, I have found that they are not always the best, and that the point upon which we must rely is the *viscosity*.

How to Test the Viscosity of Oil.

To test this I have found a French pourette graduated into 100 c.c. to be most useful. The pourette is fitted on a stand and filled with the oil to be tested; after allowing all bubbles of the air to separate, it is permitted to run through, and the time it takes to do so is carefully noted. At the close of the experiments it will be found that the viscosities are directly proportional to the time taken: thus if a mineral oil takes 15 seconds and rapeseed oil 45 seconds, the viscosity of rapeseed oil is three times that of the mineral. The temperature may be either 60° or 90° Fahr, but the latter is preferable, as the oil may be subjected to that temperature when in use. The question next arises, how is this viscosity basis to be applied? If an oil of very high viscosity, such as castor or rapeseed, were used to lubricate an engine of low horse-power, we should in all probability find that, instead of reducing the friction to a minimum, it would itself become a source of resistance and increase the evil. And conversely, if an oil of very low viscosity were, used to lubricate an engine of high horse-power, we shall find that the friction would be but slightly, if at all, reduced. Hence, when we come to look at extreme cases, we see that there exists a very marked connection between viscosity and horse-power. A high viscosity is not suitable for a low horse-power, and conversely, a low viscosity is not suitable for a high horse-power. And just as the case holds for these extremes, so does it hold for every point between them; the viscosity must always keep parallel to the horse-power.

How to Render Oils more Viscous.

The same rule holds with respect to machinery, and to insure perfect lubrication the viscosity must gradually increase with the ponderousness. From this it is clear that economical lubrication does not consist in procuring and using the thickest oil possible, but the oil that is best adapted to the nature of the machinery, and scientific mixing likewise consists in compounding oils most clearly adapted to the purpose for which they are to be used. It is rather difficult to say what oils are most suitable for mixing purposes, but it may be stated with a tolerable degree of accuracy, that the best method is to take a basis of American or Scotch mineral oil, 885° to 903° sp. gr., and add either olive, lard, rapeseed, or castor, to "work up" the viscosity. Olive and lard, when mixed with mineral in proportions 10, 20, 25, and so on up to 75 per cent., are about equal in value as lubricants of the lighter class of machinery. Rapeseed oil in like proportions is valuable where the machinery is of a heavier kind, or where the lubricant has to be used throughout a works in which the machines vary much; but in such a case it will be better to divide them into classes and use a special oil for each class. Castor-oil mixed with mineral in varying proportions may be used in the case of the most ponderous machinery.

An Interesting Phenomenon.

In mixing castor I noticed a remarkable and interesting phenomenon. On adding about 25% to an American neutral oil of a reddish color, I was surprised to find, after the lapse of a few hours, that the oils had separated, and that the castor, originally quite clear, had taken down with it nearly the whole of the coloring matter, leaving the mineral oil a beautiful pale, straw-colored liquid. I further found that the successive additions of fresh castor still further removed the coloring matter, until both castor and mineral were of the same tint. Continued experiments showed that if the castor were first mixed with an equal bulk of olive or rapeseed oil, and then added to the mineral, the mixture was of a permanent character.

In conclusion, I have found that a properly-mixed oil is in every case far preferable for general use, to either mineral, olive, lard, castor or other oil used singly; and it may be added that no oil is more suitable as a basis for mixing than mineral, and that cold-mixed oils are better than those mixed at a temperature over 100°.

Progress in Machine Construction.

The recent stimulus of abundant orders for all kinds of shop tools, engines, boilers and railroad equipments has greatly encouraged improvements in machinery. A prolonged feverish demand for shop tools and motors for manufacturing establishments might have been expected to repress almost any tendency to innovation of design while such a state of trade should continue, but the result has been to check little more than those questionable changes, such as seem to conflict with generally-received principles of correct mechanical practice. With a steady and profitable demand for the output of shop, mill or factory, proprietors are naturally averse to trying any doubtful experiments with machinery or fixtures. To this fact, in a great measure, is due the reliable and permanent character of most mechanical devices introduced and applied by established concerns within the last 12 months. Our columns have from week to week borne numerous evidences of progress in designing and building lathes, upright drills, planers and shapers, milling machines, gear cutters, stationary steam engines, steam pumps, locomotives, steam generators, and special machines for a wide variety of purposes.

An accelerated demand for these productions, of the exact styles now turned out, does not seem to have prevented reasonable and desirable changes, nor is it probable that it will do so in the early future. Reward or condemnation, in these busy times, is almost sure to follow swiftly the introduction of mechanical innovations.

Thus far there has been very little danger of an over-production in any class of shop equipments. The real trouble has been, and still is, to obtain within any reasonable time the tools and supplies needed in machine shop work. Electric lighting is very much retarded by the unavoidable delay in securing engines and dynamo machines, to put new plants into operation, and railroad and locomotive shops are seriously inconvenienced by waiting so many months for heavy tools and equipments, there being but few establishments in this country making a business of building such tools.

With a hundred thousand miles of railroad in the United States, and with extensions going forward at a rate never before known, the need of special heavy tools for railroad shops is likely to increase faster than the facilities for supplying that need, especially as it would require months, if not years, to fit out a new shop and make ready to turn out machinery of this class. —*American Machinist.*

The Pro and Con of Brakes.—Some portions of a well-considered and carefully-written article on "Brakes," which has recently appeared in one of our English exchanges, may be of interest to our readers. After describing the leading styles of brakes to be seen upon both English, German and French vehicles, the writer says: Brakes, though possessing many advantages over the old "dragshoe and chain," are open to many grave objections. They often lengthen the carriage and increase the draught, by causing the hind wheels to be placed further back than they otherwise would be, in order that the doors may clear the brake-blocks. In certain carriages this objection is avoided by hinging the doors to open in the opposite direction, thereby exposing ladies' dresses to the mud that collects on the tires and brake-blocks. In all carriages the hind springs are, during the application of the brake, temporarily useless. The pressure necessary to generate sufficient friction for the brake-block to "hold" the wheel doubles the strain on the hind carriage, caused by the wheels sliding instead of rolling. When, as frequently happens, a brake has to be fitted after a carriage is finished, new, longer, and stronger pump-handles have to be made, involving expense and delay. A want of modern carriage building is a brake that shall be equally as easy and convenient to use as the present brake, that shall *not* increase the draught of a carriage, that shall *not* disable the hind springs during its application, that shall *not* involve expensive alterations to finished carriages; in short, a brake possessing all the advantages of the present brake, with none of the drawbacks cited above.—*Blacksmith and Wheelwright.*

Scientific Progress.

Respiration in the Mammalia.

The rapidity of the respiratory movements in man is about one inspiration to four heart-beats, or fifteen to twenty-five per minute; greatly varying, however, according to age, sex, and circumstances. In animals with high temperature, breathing is much faster, becoming almost a tremor in birds. In the whale, on the contrary, breathing is suspended while the animal is under water; it being provided with reservoirs of pure blood. When the latter is exhausted, the creature comes to the surface and puffs and "blows" to obtain air and refill the reservoirs.

The difference in color of the blood of vertebrates is chiefly due to the varying amount of oxygen in chemical combination with the hæmoglobin of the red corpuscles—the brightness of color being proportionate to the oxygen. An essential part of the hæmoglobin is iron; and it has been supposed that the change in color is due to a chemical change from a ferrous to a ferric salt. But this simple and plausible explanation is now denied by eminent physiologists, who, however, admit that the iron has some essential but unknown influence. A minor cause of the darker color of the blood is the swelling of the corpuscles by absorption of carbonic acid.

The corpuscles are the oxygen-carriers, seizing the oxygen in the lungs and conveying it to the tissues, where it unites with the carbon and hydrogen. The corpuscles also convey carbonic acid to the lungs, but they divide this labor with the serum.

In large quantity, carbonic acid acts as a narcotic poison; for, on account of its superior attraction for the hæmoglobin, it replaces and excludes the oxygen. Other gases, as nitric oxide, have the same effect. Nitrogen, on the other hand, is entirely negative in its effect on the blood, and consequently serves to dilute the oxygen of the atmosphere, without injury to animal life.

More oxygen is inhaled than is exhaled as a component of carbonic acid. The extra amount doubtless unites with hydrogen to form a portion of the exhaled water, and to produce sulphuric and phosphoric acids.

The human lungs exhale, in 24 hours, about two pounds of carbonic acid. This is the product of the burning of nine ounces of carbon. As giving some idea of the forces within the body, it is interesting to know that the combustion of nine ounces of carbon liberates over 6,000,000 foot-pounds of energy. This is equivalent to more than one-eighth of a horse-power acting continuously for the 24 hours; or it equals 182 horse-powers working for one minute.

Relation of Atmospheric Resistance to Temperature.

Hirn has presented a memoir to the Belgian Academy in which he gives the results of numerous experimental researches upon the relation which exists between the resistance of the air and its temperature. The hypothesis of Clausius, upon the constitution of gases, was supposed to furnish the means of calculating their resistance *a priori*, but upon attempting to establish the formula experimentally Hirn was unable to obtain the results which he anticipated. The memoir was submitted to the examination of Messrs. Folie, Van der Mensbrugghe and Melsens. The committee were unanimous in recommending its publication and in expressing the belief that its startling conclusions would be likely to awaken much profitable criticism and discussion, but Melsens was the only one who was prepared to adopt Hirn's conclusions and to admit that they would be likely to require a re-examination of some of the most important conclusions of thermodynamics. Hirn thinks that he has demonstrated that temperature has no influence upon the resistance of gases, that gaseous temperature and pressure cannot be explained by the movements of material atoms, and that it is impossible to give any satisfactory explanation of molecular phenomena without assuming an immediate dependence upon spiritual influence.—*Bull. de l'Acad. de Belge.*

Effects of High Barometric Pressure.—Careful simultaneous observations at different points appear to indicate that barometric pressure may sometimes affect the ocean level. Some noteworthy phenomena occurred during a recent season of high barometric pressure over southern Europe, which have been alluded to as follows: At Antibes (a seaport in the south-east of France) the sea level was depressed about a foot, laying bare portions of shore over which boats can usually sail, and exposing surprised sea slugs and other marine animals to the direct rays of the sun. This continued about a fortnight, and is attributed by M. Faye to the high air pressure. Again, Gen. de Nonsouty reports from the observatory at the top of Pic du Midi that the lowest temperature there this winter has been only 5° C., and during the recent high pressure, from January 8th to 20th, the air being in a state of exceptional purity, temperatures as high as 26° C. were registered. The highest at Bagueres-de-Bigorre is considerably short of this, so that we have here an inversion of temperature with altitude. The General states further, that from the 1st of January the zodiacal light was distinctly made out; probably this has never happened before in our climates, so near the winter solstice. Once more, the General and his assistants, on January 20th, at 6:30 P. M., saw distinctly the earthshine on the moon and the thin crescent, though only 25 hours 46 minutes old.

The Expanding Power of Ice.

In a recent number of *Nature*, Mr. Bergh has drawn attention to the powerful agency exerted by ice in severing rocks, of which he gives a striking instance occurring on the Aalesund, in West Norway, where a low ledge rising out of the fjord is all that remains of a once extensive fjæld promontory, which, in the year 1717, was suddenly blown up and precipitated into the water by the force of the ice within the interstices of the stone. The winter had been mild, and during a rapid thaw a considerable stream had welled up from the ice-covered summit of the fjæld, and carried its waters into every crevice of the rock, when a sudden change of wind brought about a sharp frost, which turned the descending waters of the newly formed stream into ice, arresting their course within the interstices of the rock. The result was the explosion of the entire mass of the fjæld below the outbreak of the stream, and its projection from a hight of more than 1,500 ft. into the neighboring fjord, which ingulfed the whole of the promontory with its cultivated fields and farmstead. Simultaneously with the disappearance of the land below the surface of the fjord a huge mass of water was propelled against the opposite shore, carrying with it rusty anchors, boat rafters and numerous other objects which had long lain at the bottom. The disturbance extended a mile beyond the point at which the land was submerged, and the waters in retreating carried with them a wooden church which had stood 50 ft. above the fjord, besides sweeping away all the fishing boats for a distance of two and a half miles. Before this occurrence, which was attended by loss of life to about a score of persons, the headland had been much resorted to on account of the halibut which abounded in the neighborhood, but since that period the fish has never returned, a circumstance which, according to local popular belief, is due to the covering up by the infallen rock of certain submarine cavities and springs frequented by the fish.

Mental Distance of the Moon.

M. Plateau lately sought to estimate the distance to which the moon is mentally referred in the sky, by getting some one, after looking at that body, to project the accidental image on a wall, then move to or from the wall till the diameter of the image seemed equal to that of the moon; and he obtained the distance 51 meters. Again, Prof. Thirion, of Namur, got twelve students to draw on a blackboard a circle the size of the moon as it appeared to them. The circles varied from 19 to 79 cm., mean 32 cm., and it was inferred that the moon was mentally referred, on the average, to about 35 meters. Dr. Charpentier, by still another method, obtains the value 12.9 meters, so that there are great differences, and in any case the distance is much less than might have been thought. M. Plateau has, says *Nature*, further applied accidental images to finding the distance to which the imaginary celestial vault is referred. A spot in a white square of paper on a dark ground was looked at steadily at the side of an open window for twenty seconds, then the person looked skywards, above the opposite houses, then to one of these houses, and compared the size of the accidental images in either case. The sides of the two were by one person estimated as 5 to 6, by another as 4 to 5; and the width of the street being about 30 meters, the distance assigned to the celestial vault is inferred to be in one case 30, in the other 29 meters. A similar result was got by night.

Improved Lenses for Telescopes.—A Georgian of scientific attainments, residing at Darien, thinks he has discovered that lenses for telescopes can be manufactured from the virgin drip of resin. The largest lense made of glass is only 30 inches in diameter. This magnitude can be greatly increased by the new method, and, consequently, there is no telling what wonderful astronomical results may flow from its adoption. The main difficulty is in securing a favorable opinion at headquarters here. I have called the Hon. George R. Black's attention to it, and he has promised to see Prof. Baird and urge him to make or have made competent investigation. My Darien correspondent is unfortunately not situated for pushing his discovery, and I can only aid him with my pen and tongue. He reminds me, and I repeat it for public edification, that no less a person than Mr. Calhoun stood in the way of Prof. Morse's electric telegraph, and Mr. Stephens says that he was the only Southern Congressman who stood by Morse through thick and thin. Gentlemen who are conversant with science assure me that the Darien discovery is worthy of a thorough test, and, as it will not cost much to make it, I hope this notice may meet the eye and open the purse of some man or woman, who thereby stands a reasonable chance of being connected with a tremendous possibility.—*Washington Letter.*

The Mining Share Market.

As usual, very little doing in stocks. The principal item of interest has been the proceedings of the meeting held this week among the managers and superintendents of the flooded Gold Hill mines, to devise ways and means of extracting the water and resuming explorations. There were present representatives of the Bullion, Exchequer, Alpha, Imperial, Yellow Jacket, Crown Point, Belcher, Ovorman and other companies. Colonel C. L. Weller, of the Crown Point company, presided as Chairman. W. H. Patton, superintendent of the north end mines, whose judgment and advice had been requested in the matter, presented a chart of the underground workings of the flooded mines, and gave some statistics to show the quantity of water which now fills them. The present daily influx amounts to 1,900,000 gallons. The Yellow Jacket pumps have a capacity for extracting 1,382,000 gallons per day. He suggested that the Belcher and Crown Point pumping machinery he moved to the Ward shaft. This would increase the pumping capacity to 3,000,000 gallons per day, to say nothing of the hailing facilities. If this were done, the water could he extracted down to the 2700 foot level in a time not to exceed six months, and at a cost not to exceed $500,000, which could he divided among the ten or more companies in just proportion. It would cost about $20,000 to move the Belcher and Crown Point pumps. They could he purchased, he thought, for about $150,000, and the cost divided, Crown Point and Belcher to receive oredit therefor, etc. On being asked if he did not think a hydraulic pump at the Yellow Jacket shaft would do the work better and cheaper, Mr. Patton said that it was a mistaken idea that hydraulic pumps were more economical and better for general mining uses than the Cornish pumps. In proof of this he said that the Cornish pump at the Union shaft does as much work on a consumption of three cords of wood as does the hydranlic pump at the Combination shaft on four cords. The hydraulic pump was impracticable for sinking and general mining. A committee, consisting of Messrs. Patton, Taylor and Foreman, was appointed to draft a plan for submission to the different companies. The repoit will probahly he made within two weeks. From all that could he observed, the mine managere mean bnsiness, and their efforts will he appreciated by the puhlic. In the course of his remarke, Mr. Patton spoke very favorahly of the showing for a new honanza in the north end.

THERE were several Black Range men in the city yesterday. They give good accounts of the mining interests down there, and do not believe that there is a hostile Indian in the country. The miners are highly pleased at Prof. Sileman's account of the country, delivered at the American Institute of Mining Engineers at the recent meeting in Washington. They say that they have the "stuff" and are glad that the fact is hecoming known in the East.—*Silver Brick, N. M.*

Academy of Sciences.

The regular meetiog of the Academy of Sciences was held on Monday, and the following life members were elected: John F. Boyd, Hermann Schussler, John W. Ackerson, Daniel E. Hayes, W. S. Keyes, James H. Goodman, Jacob Z. Davis; and resident members: Prof. Wm. T. Reid, President of the University of California; Prof. J. J. Rivers, Prof. Henry A. Ward, M. H. Hecht and Thomas Brown. The followiog donations to the musenm were presented: From R. H. Stretch, petrified wood and leaves; from Col. Batchelder, U. S. Depot Quartermaster, a large hlook of stone, in which are imhedded large animal bones, found on the Encino rancho, Los Angeles; from James Melrose, obsidian arrow point, from north side of Napa Valley; from W.G. W. Harford, a large horned toad; from Dr. H. W. Harkness, a pandelus, or large-sized speoies of prong-like animal from Anaheim; from Mrs. M. H. Metrose, a fine collection of four-stone mortars and pestles from Livermore valley; from Mrs. Hostetter, of San Jose, a mass of post-pliocene cretons, or sea shell eet in hard sandstone, found in the mountains; from W. T. Notie, a deer's head mounted. A large number of exchanges and donations to the library were received.

An official communication, incloeing a reeolution from the Board of Snpervisors, was read, requesting the Academy to make an investigation of the question of sewer-gas, reporting upon it hy lectures to be pnhlicly delivered, or hy manuscript report, reviewing its engineering, microscopic and chemical conditions, and bearing upon the present exceptionally high death-rate; provided, however, that all this be done without cost or expense or expenditure of any kind or natnre whatsoever to the city. The committee appointed to consider the matter consisted of Col. Geo. E. Gray, Dr. H. Herman Behr and Justin P. Moore, who were given power, if necessary, to add to their nnmber.

Dr. H. W. Harknese reported the receipt of a very curiously colored deposit, which had been found precipitated in a hottle of Mono lake water, which was taken from the lake over a year ago, and hae stood perfectly still since that time. He gave notice that he should read a paper upon it at the next meeting, and would illustrate it by the use of microscopes.

The matter of the presentation of the Ward collection to the Academy hy Messrs. Crocker and Stanford, is referred to in another colnmo.

THE complete results of 10 days' run of the Philadelphia Mining and Smelting company's plant at Ketchnm, Wood River, Idaho, were $23,245.50 in silver bullion, $9,395.82 in lead, and $541.80 in gold hars. The smelter will resume operations ahout the middle of May.

THERE is every indication that the price of lead will keep up, and there will be great demand for lead ores in the Salt Lake market this season.

MINING SUMMARY.

The following is mostly condeneed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

BUTTE.

DEER CREEK MINES.—Butte *Record*, April 1: Myron Dorn, John L. Jones, Charley Jennings and Joe Baxter arrived in Chico this morning from the Deer Creek mines. They left the mines early yesterday morning and walked to Vina, a distance of 30 miles, ou the old Deer creek trail. The mines here closed down until the 1st of May. It was impossible to get provisions to the mines, except hy pack-mules or on snow shoes, and by that way food would he too dear. Mr. Dorn informed a *Record* reporter that 15 men bad heen kept steadily at work in the mines during the past three months. Two "giants" have been constantly used, and a fair clean-up has been made. There ie a good water supply for these mines from Butta creek, which flows the year round. The great difficulty to overcome is a bed of lava, from 15 to 20 ft through, which covers a rich stratum of pay gravel. Work during the winter has been confined principally to the Lava Queen claim, but when operations begin again in May a three-mile flume will be built to the Jackson mine, and the working force will be largely increased. These mines are under the management of Mr. George C. Spooner, a miner of considerable experience. The mines are owned hy a company of Boston capitalists, who have sunk large sume of money in their claime. It ie thought by some that the mines are worthlees, hut an old miner informed a reporter this morning that, in his opinion, they are rich and would shortly develop into a bonanza for their owners. It waa rumored in town that the company bad suspended and refused to pay their employees any wages due them, hut inquiries at the bank of Chico this afternoon prove the reports to be false, as the company is a reliable one and pays all debts promptly.

CALAVERAS.

DITCH REPAIRING.—Calaveras *Chronicle*, April 1: The canal of the Mokelumne & Campo Seco Water Co. is agaln carrying a full head of water. The last storm, which was an unueually severe one, caused heavy land slides in the mountains, doing no small amount of damage to ditch property. In the Water Co.'s ditch no very serious breaks occurred, but a number of slides took place, filling up the ditch and cutting off the supply of water for a number of days. One slide so filled the canal with soil and huge rocks that it took 20 men 4 days to clear it. All thie, of course, interfered with those mining operations which are dependeut on this source for their water supplies. Everything is now in order and runuing, and it is not likely that any more such delays from the same cause will occur again this season.

EURREA AND PINE PEAK MINES.—The Cook Broe are making a very successful run at their Eureka mine. With 600 inches of water, under a high pressure, working hoth day and night, they have succeeded in removing a large body of gravel. At preeent they are running hottom dirt and hreaking ledge preparatory for a clean-up, which, judging hy present indications, will be a bonanza. Their Pine Peak mine is developing to their entire satisfaction, and will doubtless prove to be one of the best properties in the county. We are creditahly informed that the Cook Bros. are now at work on a canal to convey water from the Mokelumne river to the Pine Peak country, and will this spring put on a large force to accomplish this object. Had we a few more such energetic men in the community many of our mines now abandoned would be running.

LEG BROKEN.—A mining expert from Oakland had his leg broken by falling about 20 ft down the shaft of the Lone Star mine, near Wcet Point, one day last week.

EL DORADO.

CLIPPER.—Georgetown *Gazette*, March 31: Work has been started on the Clipper quartz mine, under the superintendence of Mr. Powning. The water has just been pumped out, and the mine is being put in shape for etarting up the mill and extraction of ore. Under the management of Mr. Powning, we are confident that the Clipper will he made to pay handeomo dividends. This mine is about three miles northeast of town.

ARGONAUT.—Supt. Hopkins, of the Aultman M. & M. Co., and Mr. John Smith, one of the late owners of the Argonaut mine, near Greenwood, were in town Thursday. The ten-etamp mill on the Argonant is now running day and night.

INYO.

DEEP SPRINGS.—Cor. Inyo *Independent*, April 1: This well known mining district is not in its feet throes of death, but is steadily coming to the front with its vast mineral resources. Mr. James Croes, a mining man of vast experience throughout the Pacific coast, accompanied hy a wealthy capitalist from San Francieco, paid the district a visit last week, examining propertiee. The Half Dollar owners are sinking their shaft at a lightning speed, and winding up the company's business at the preeent depth is no easy task. M. J. Byrnee is making exteneive preparations to resume work on the Trade Dollar. Mr. Elise, of the Mayrock, has struck a fine bunch of high-grade metal. The Oriental mine, engineered hy Messrs. Jordan and Black, is looming into prominence. The prospecta for a general boom in this section are favorahle. You have had your Bodie, Bodie, Tombetone, and snide stock boom on the Comstock, but ours will assume a different shape. It will he hullion conetantly hooming out of the district.

NEVADA.

THE PUMPING MACHINERY.—*Tidings*, April 1: A *Tidings* reporter visited the Idaho mine recently for the purpose of seeing the new pumping engine at work. The machinery was found working eo noiselessly that when one's back is turned he could scarcely believe he was eo near a ponderous engine pumping water from a gold mine 1,300 ft in depth.

THE EMPIRE.—The Empire mine is now taking out quartz from the 5, 9, 10, 11 and 13 level', the 13-level producing, hesides good milling ore, some very rich specimens. The 13-level has 200 ft of tracke, and the pay chute pitches south.

FORD AND MULLEN.—The Ford and Mullen company, located on New York hill, are having a crushing of 30 loads put through Southern's mill. It is estimated by competent judges that this will go $150 to the load. Rich specimens are still coming out of this mine.

EAST EUREKA.—Work will he commenced on the East Eureka, or O'Connor mine, on Monday next. Twelve men, all tributers, will sink down upon the ledge and take out rock for crushing. Experienced millwrighte are now making estimatee for putting the mill in repair, and work to that end will soon he commenced.

THE WASHINGTON.—The Washington mine, which has been idle for about three months, will etart its machinery on Monday, and commence the work of pumping out the shaft, which, it is thought, will take but a ehort time, as the pumps and machinery are all in first-class running order. The machinery at the Washington was inefficient, at first, to do the work required of it, but now it has been reinforced eo ae to meet all demande upon its power. Ae eoon as the water is out drifting will be commenced on the 250 level.

KNIGHTS OF MALTA.—This property has been lying idle for eome time, hut we are informed that New York capitalists will handle it this season. The last rock taken from the mine was of excellent quality, and eome of it may be seen at Moore's blacksmith shop on lower Mill street.

MAMMOTH CONSOLIDATED.—The Mammoth Consolidated mining company have organized, J. G. Jones, President; H. Davis, Secretary; Board of Directors, J. I. Meek, A. P. Tietjen and John Lnuday. The company will commence operations at an early day on the several ledges.

NEW YORK HILL.—Work at the New York Hill is going steadily along, no new developments being made since our last report.

NAPA.

THE MINES.—*Calistogian*, April 3: The weather has been unfavorable for miners to travel from town to the mines and back, consequently little prospecting has been done and no new developments of importance made, either at the surface of the ground or under it. Work has been discontinued in the north and south drifts on the 150 level of the Twin mine, in order to drift north and south on the vein at the 100 level, or each way from the end of the discovery tunnel and at the top of the shaft. This course has been considered advisable to further prove the vein at that depth, though there is scarcely a doubt but that good ore will be found in abundance. The lower drifts, above referred to, were discontinued because it was not considered necessary to prospect the vein further there at present. The faces of the drifts were in good milling ore when work was discontinued, and good ore was found the whole distance passed through. The Bonsalle are anxious to have the shaft sunk 100 ft deeper to further prove the vein, but as the work is paid for now by those who have bonded the mine, and who also give orders, this course may not be pursued at present, though the shaft will, no doubt, be sunk deeper in the near future, especially after a mill has been erected. J. J. Johnson will soon recommence work in the shaft on the Old Discovery (formerly Palisade) claim. This shaft is located a few yards a little east of north from the entrance to the discovery tunnel of the Twin mine, and is at present down a distance of 40 ft.

PLACER.

YANKEE JIM'S.—Cor. Placer *Herald*, April 1: The "beautiful snow" is entirely gone, and hydraulicing has commenced. The Georgia Hill M. Co. and the Gilbert boys are washing. Both claims are working a small force of men. The St. George M. and M. Co. have suspended work for the present. The Napoleon mine is putting on quite a strong force. I understand they are getting up a new crushing mill, which, according to all reports, will be on the ground to-day or to-morrow. A new mine, the "Bald Eagle Tunnel," about one-half mile east of this place, has recently been opened. They will work only two or three men until they get the tunnel open; then, I believe, they are to put on a larger force.

PLUMAS.

RICH QUARTZ.—Plumas *National*, April 1: From Mr. R. E. Garland we learn that a strike of exceedingly rich quartz was made in the tunnel of the Taylor Plumas mine at Crescent last week. The mine is owned by an incorporation, Mr. M. B. Bransford being in charge of the work. Garland says they brought out a candle-box full of quartz which "was more gold than quartz." They have been getting rich rock there all winter, but nothing like the present bonanza. The owners are jubilant over their good prospects, as well they may be. Send us a good cabinet specimen, M. B.

NEWTOWN FLAT.—We were shown, the other day, a clean-up from a small pile of pay-dirt washed from the claim of Leavitt & Brown, at Newtown flat. The gold was nearly all coarse, exactly like that which comes from the Manson & Corbin claim in Elizabethtown. The amount was about $117, and there was not more than $20 in fine gold, the balance being in pieces weighing from one dollar to an ounce. They certainly have the regular lead gold, and it is also certain that they have a very extensive deposit of it. When the water season is a little further advanced they will make some clean-up that will be worth looking at. There is lots of dust in that country, and much of it will come to light this summer.

SHASTA.

FROM WHISKEYTOWN.—Cor. Shasta *Courier*, April 1: As we meandered through the classic precincts of Whiskeytown and arrived on Main street on an afternoon of last week we observed an unusual bustle and stir. On inquiring as to the cause, we were directed to Woodward's hotel, where we discovered Messrs. Zent & Eastman with hats off and sleeves rolled up, deeply interested in a mortar, pan and a chunk of gold that weighed $1,100. All told, that afternoon they got over $1,000 in 2 hours' work. Since then they have been getting $100 or $200 a day. Their find is situated about 1 mile northeast of town. It will undoubtedly revolutionize prospecting in this part of the country. There is a ledge of slate, heavily timbered with iron, running northeast and southwest for miles, and it has been known that all the gulches fed from this have been very rich, but it has been left for Zent and Eastman to find a pocket where a stringer of quartz butted an elbow of the iron or slate ledge. Some think from mountain ie a continuation of this ledge. Everybody is prospecting now; miners, mechanics, merchants, clerks, boys, dogs, and even the school master has been sent on the war path. A number of good prospects have been found, but we believe Mr. Banghart's, of $1.50, is the best so far. Whiskeytown has not been dead, only sleeping.

GOLD.—A few weeks ago Bonham, a miner on Flat creek, found a piece of gold of 12 ounces, and this week Frank Joseph found in his claim a piece about 3 inches long, 1½ inches wide and half inch thick, mixed with quartz and containing about 5½ ounces of gold.

OLNEY CREEK, southeast of town, on which so many "big strikes" were made in times past, was prospected in 1854 by J. O'ney, Geo. Joseph Lane and Robert Scott, brother of our townsman, J. V. Scott. Major Reading also mined on the creek in the spring of 1852 for a short time. The stream was named after Olney.

ELECTRIC MACHINE.—Mr. Howell, proprietor of an electric machine for the discovery and location of gold and other mineral, is now operating in this county. The machine is said to work wonders in the way of indicating where deposits of gold and silver lie, and it might be a good plan for the Assessor to use the instrument in his business with our capitalists.

SIERRA.

SCALES DIGGINGS.—Cor. Sierra *Tribune*, March 30: I. P. Lloyd came down from the Iowa shaft to-day. He says there is about ten feet of snow on the level at the shaft.

SIERRA BUTTES.—No. 0 tunnel of the Sierra Buttes mine is shut down on account of a lack of water in the ditch above. The Bald Mountain company has an abundant supply of water at present for washing purposes, thanks to old Sol. H. Raymond was down from the Seventy-six mine last Monday. He says there is about 12 ft of snow at the Pliocene shaft. No damage was done at the Savage mine during the recent storm. Several slides had occurred at the mine, but fortunately they missed the buildings.

NEVADA.

WASHOE DISTRICT.

UNION CONSOLIDATED.—Gold Hill *News*, April 3: East crosscut No. 1 on the 2700-level has been extended 20 ft, and north drift No. 3 has been advanced 25 ft. The joint Sierra Nevada east winze has been sunk and timbered 10 ft. In the main south lateral drift are easing timbers. During the past week there have been extracted from the 2500 and 2700-levels 315 tons and 1,300 lbs of ore.

SIERRA NEVADA.—On the 2500 level the winze in east crosscut No. 2 has been sunk and timbered 10 ft; north drift No. 2 has been advanced 27 ft, and the main north lateral drift 32 ft. On the 2700 level, main north lateral drift No. 1 has been extended 20 ft, and north drift No. 3 has been advanced 25 ft. Joint Union Consolidated east winze has been sunk and timbered 10 ft.

OPHIR.—Are cutting out a drain in and timbering up the main south drift on the 2700-level. On the 2900-level the main south lateral drift has been extended 25 ft. During the week 130 tons and 400 lbs of ore have been extracted from the croppings, and 438 tons and 130 lbs have been sent to the mills.

FOREST.—The southwest crosscut was advanced 50 ft; total length, 168 ft. The ground passed through has been quartz and clay, which was soft and required timbering. On Friday night about an inch and a half of water was struck in the face of the drift.

HALE & NORCROSS.—The northwest drift, 2500-level, has been advanced 30 ft during the week; total length of drift, 429 ft. Have started a drift running north at 165 ft from winze, which is now in 27 ft.

GOULD & CURRY AND BEST & BELCHER SHAFT.—On the 2300-level the Best & Belcher northwest drift was advanced 45 ft; total length, 610 ft. The joint shaft was sunk and timbered 56 ft; total depth, 2,235 ft.

MEXICAN.—On the 2700-level the main north lateral drift has been extended 28 ft, and the main south lateral drift the same distance. On the 2900-level the main north lateral drift has been advanced 27 ft.

CONSOLIDATED VIRGINIA.—On the 2500-level south drift No. 2 has been extended 31 ft. On the 2700-level the south drift drill-hole has been advanced 150 ft.

UNION SHAFT.—Are putting in a pump-bob at the 2600 station and repairing the 1600 drift to the Mexican and Union Consolidated winze.

UTAH.—Timbering and repairing at the head of the incline. On the 2500-level the main south drift has been advanced 22 ft.

CHOLLAR.—The west drift was run 40 ft; total length, 106 ft. The ground in the face is the same as reported last week.

CALIFORNIA.—On the 2700-level the main south lateral drift has been extended 20 ft.

BRISTOL DISTRICT.

MONITOR.—Bristol *Times*, March 25: The Monitor mine, owned by Bob Wilson, gradually grows more valuable as work progresses. It is thought that this will one day become one of the richest mines of the district.

ORE.—Teams will soon be put on hauling ore from the Day mine to the furnace, which will be started up some time next month. The way the Day looks now, there is enough ore in sight to keep four stacks running for years. The ore in the Mayflower is still coming in big, but not quite of as high a grade as formerly, though the showing is larger than at any time heretofore, and enough ore is in sight to keep the mill in constant operation for years.

MILL.—The Bristol company's mill started up again last Saturday, after a stoppage of a few days on account of an insufficiency of water, but now have a plentiful supply on hand, and everything is in and about the mill in ship-shape order. Mr. Goodhue, of the Bristol S. M. Co., informed us that he will sink another 100 ft so as to overcome the inconvenience attending the lack of water. Work will be commenced as soon as pumps arrive, and it is hoped that the difficulty will thereby be done away with.

DAY.—We have been informed that the crosscut running east from the bottom of the shaft in the Day encountered a huge body of ore not more than 20 ft from the drift. We have, as yet, been unable to learn anything authentic concerning this late strike, but suppose that it must be on the 700—the tapping of the bonanza on the 620.

MACHINERY.—J. T. Gilmer and O. J. Sallebury were here all last week, taking a look at their different mining properties, and are more than well satisfied with the showing. Men have been put on on both the Iron and Tempest mines, and developments will be prosecuted with all possible speed. Many tons of machinery for these two mines are on the road from San Francisco, and ought to arrive here some time this coming week.

COLUMBUS DISTRICT.

NORTHERN BELLE.—*True Fissure*, April 1: Work in the main shaft has consisted of completing the timbering and putting in the guides, enabling the hoisting of the cage to the fifth shaft level. At this point the station is completed, and a drift started to connect with the main winze now being sunk from the fourth level. This winze is now down 137 ft on an incline. The adit and the levels above show very little change, but keep up the usual production of ore. The daily yield of ore has been about 50 tons. Bullion shipments for the week ending March 30th have been $15,739.70, and a total of $58,847.72 on March account to the same date. One more shipment remains to be made on last month's account.

MOUNT DIABLO.—The stopes above the east drift on the third level are showing improvement, and the one below the north crosscut on the same level, in the west drift, is looking much better. The stope from the west winze, on the second level, continues to show well, and that near the center of the mine, on this level, opens well and is yielding considerable high grade ore. The old workings have been broken into from the foot of the stope east of the shaft on the first level, but a small streak of rich ore is being followed in the hanging wall, which looks promising for opening. All the stopes on this level, to the west of the shaft, are looking well. A shipment of bullion amounting to $6,082.83 was made on the 25th ult., and another of $7,496.25 on the 28th.

GENERAL JACKSON.—The work at the bottom is progressing as usual. A limited quantity of ore is being extracted, but of very good grade. In extending the drifts good ore will, no doubt, be found.

EAST MOUNT DIABLO.—The north crosscut on the third level is in very favorable ground, and has been driven 15 ft during the week.

CORY DISTRICT.

THEY GO DOWN.—Esmeralda *Herald*, March 25: The doubt existing at one time as to whether the ledges in this district continued down to any depth, has been removed, we are informed, by the recent cutting of the Big Indian ledge in their lower tunnel about 1,000 ft below the croppings. The company's mill is running night and day and turning out bullion. The success of the Big Indian is assured, and before long five more stamps will be added to the mill. The whole district is alive.

GARFIELD DISTRICT.

PROSPECTS BRIGHTER.—Candelaria *True Fissure*: The mining outlook in this district is growing better and the prospects brighter. The Lottie mine, owned by Johl & McDonald, is producing some very rich ore. Three carloads were recently shipped which went up in the thousands, and two carloads, of the same quality of ore, still remain on the dump ready for shipment. The Delaware No. 3 is producing rich ore, a shipment from which will be made in a few days. The Yerrington & Bliss mine is located about one mile south of the Lottie. Tools and provisions have just been hauled to the mine, and active work will be commenced in a few days. Taken altogether the prospects of Garfield district are looking very bright, and before the summer will be far advanced it will be full of miners and prospectors.

GILLIS DISTRICT.

ORE.—Esmeralda *Herald*, March 25: In Gillie district, Clem Ogg is working six men, taking out ore from his mine. Mr. Benton, of Luning, has some men at work in this district.

LAKE DISTRICT.

FLATTERING OUTLOOK.—Eureka *Sentinel*: The outlook of this district is very flattering for the coming summer. Prospectors are scattered from one end of the district to the other, and some of the claims now being worked promise well. The C. & C. railroad are hauling ore to Dayton at a low figure, thus giving the prospector a chance to thoroughly test his property at a small outlay of capital, and at the same time encouraging men to go into the district and look for mines.

LEWIS DISTRICT.

BETTY O'NEAL.—Lewis *Herald*, March 20: The south drift in the Betty O'Neal mine has been driven ahead during the week, the ledge increasing in size, and rich ore being taken out. In the upper stopes the ledge still holds its own. Crosscuts have been run below the stopes and the ledge found carrying the same quality of ore as above, and increasing in size as run further south. The force has been increased, and more miners will be put on in a few days.

STARR-GROVE.—The south drift from the 300-level in the Starr-Grove mine is now in 50 ft, with a crosscut to the hanging wall, with good ore in the top of the drift. The indications are that a chimney of ore is south of the crosscut, as the ledge increases in size as the drift is driven ahead.

CHLORIDE.—The Chloride tunnel has attained a total length of 565 ft. The direction having been slightly changed, will bring it directly under the old workings. The character of the ledge has improved some since last week.

EAGLE.—The contractors on the Eagle tunnel have made good headway for the week past, and are now running under the foot wall, through the country rock. There is about 130 ft of the ledge stripped, and crosscuts will be run to the hanging wall, testing the size and quality of the ledge.

SANTA FE DISTRICT.

AT WORK.—Esmeralda *Herald*, March 25: B. G. Smith & Co. have eight men at work on the Tiptop mine, Santa Fe district, putting the mine in shape to extract ore. The company also have men at work on the Esmeralda mine in the same district. Mr. Anson has arrived from New York, and will commence operations in a short time on the El Dorado company's property, situated in the Gladdin mountains, about five miles from Luning. Of late there have been several parties trying to purchase the Mayflower copper mine from Eli Johnson, the owner, but as yet no sale has been made. Charles Chultz and Eli Johnson are taking out some rich chloride ore from the Illinois claim. They have several tons of high-grade ore now on the dump. The Illinois is the property of Col. A. C. Ellis, of Carson City. As soon as the weather will permit, Santa Fe will have many men at work. T. F. Bradley is now operating at Darlington Springs, Santa Fe district, and has several fine prospects there.

ARIZONA.

TOMBSTONE.—*Epitaph*, April 1: The combination air shaft (incline) since its connection with the stopes, creates the most perfect ventilation, the draft of air being so strong in places that a lighted candle can only with difficulty be carried through the drifts. The incline is now 85 ft deep and being still pushed ahead.

EVENING STAR.—The shaft in this mine is now down 100 ft, at which point a crosscut has been started to the east, and at 14 ft the wall of the lode has not yet been reached. The crosscut is all in good ledge matter. The width of the ore body is thought to be over 20 ft at this point.

OLD GUARD.—Shaft down 105 ft; north drift in 103 ft, and south 65 ft. The vein looks about the same as at last report. The shaft will probably be sunk to a depth of 25 ft before another level is opened up.

INGERSOLL.—Work is progressing as usual, and the output of ore remains just about the same as heretofore. The contract for working 1,000 tons of ore at the Boston mill has been signed, and its reduction will begin on Monday next.

GRAND CENTRAL.—Stopped sinking in main shaft on Wednesday, on account of strong flow of water. Water has risen to where first station stands 18 ft deep in the shaft. Development on the 600 level, old shaft, continue favorable. Shipping usual amount of ore.

VIZINA CON.—No ore will be worked during the next 30 days, for the reason the Boston mill will commence running on Ingersoll ore on Monday next.

HUACHUCA WATER CO.—Up to Friday night, 7½ miles of 7-inch pipe had been laid and 1 mile of 5-inch pipe leading to Carr canyon. There were 100 men working in 2 gangs and they lay about ⅝ of a mile per day. The pipe has nearly all been delivered, therefore there will be no delay in completing the work. Work on the telephone line began to-day and it will be completed in 12 days. Leaving the superintendent's office, there will be a station at the reservoir, back of the Grand Central, and one at the terminus at the dam, in Maple (Miller's) canyon.

CONTENTION CON.—At the Flora Morrison shaft the 600 station has been put in and a drift west run 35 ft through good ground. Connected with the Grand Central on the 500 level, yesterday, which improves the ventilation. The usual amount of ore goes forward to the mill.

ORE.—Globe *Chronicle*, March 25: On a ledge running nearly parallel with the South Pioneer, we are informed, at a depth of 60 ft ore has been struck resembling in appearance and approaching in richness that of the Pioneer. Mr. G. W. Sharp reports the finding of a copper vein 3 ft wide, of good ore, near the Oila river, about 50 miles from Globe. Also promising silver prospects in the same locality, a region not heretofore prospected. "Silver Glance," a correspondent known in Globe by his nom de plume, writes to the *Phoenix Herald* from Pioneer, in which he predicts that the South Pioneer mine will prove equal if not better than the King, and that the camp will become one of the leading mines in the Territory.

CENTENNIAL.—The Centennial mine is taking out 15 to 20 tons of ore a day which assays from $75 to $500. Mr. Geo. Beamish is now in charge of the mine, has had experience, is a practical miner, and says the mine is one of the richest in the district. We may look for developments in this property which will astonish the douhters.

IDAHO.

ATLANTA.—*Idaho World*, March 24: Ed. Ryan, who came over from Atlanta the other day, says the indications are that new life will be infused into that camp the coming summer. None of the mills there are going now, but they will be started up in a short time. The Monarch company intend to put up a roaster at their mill this season. This mill has been idle for a long time. The company have been getting their rock crushed at the Buffalo. The Tahoma is looming up, and gives promise of being one of the best mines of that district. The owners of this mine will erect a mill this season. The machinery was shipped to Kelton last fall, but it being late in the season the roads were in a bad fix, so the mill was not shipped on. The Buffalo company is getting out way up ore. Only a few men have been at work in the mine the past few months, but the force will probably be increased before long.

SNAKE RIVER PLACERS.—*Blackfoot Register*, April 1: Notwithstanding the deep snow and cold weather, a large number of placer claims have already been taken up along Snake river, and the prospect is that before the summer is half gone 100 miles along the river will have been located, and a large part of it being worked. We have been informed that there are at present 6 different companies already organized in the East, who will soon send representatives here to make investments or take up claims, and most of them will at once commence operations. A man bought a claim below here last year for $2,500, and by working it alone took out over $4,000 last season. He was offered $10,000 for it a short time ago, but refused to sell it. The company organized last year, who purchased the claim of Chas. Lane, and have taken up a claim about 7 miles up the river, is called the Blackfoot Gravel M. Co. Several parties are on the ground anxiously waiting for the snow to leave to commence constructing their ditch; the hauk there is said to be nearly 50 ft high and very rich. Other claims have been taken up above that, and still there is room. Mr. Flanuken, one of the purchasers of the Joe Warren claim is expected here in a short time. Mr. Perkine, who is connected with that company, has been here for the past 2 weeks. To Eastern companies contemplating coming this way, we will say one of the advantages of coming to Blackfoot is the Utah & Northern railroad, which will bring them here without any staging. They will find just as good accommodations here, and just as good mining as anywhere on the river.

MONTANA.

BELMONT DISTRICT.—*Inter-Mountain*, March 27: The appearance of the welcome chinook has in a measure infused new life in this district, although it will be a month yet before the snow has disappeared sufficiently for much outside work to be done. In the vicinity of the Whippoorwill mill, two strikes have been made in the past month which will help to keep the 10-stamp mill busy this season. Messrs. Hall and Lahey are taking out gold ore from the Northern Light worth $100 per ton. Lane and Lynch have struck pay ore in a claim they located last fall. The Gloster now has 60 stamps in constant operation. The entire battery of 80 stamps will be running in another month. The ore body in the Gloster holds out well on the 200 level, being as rich and free as near the surface. The Bald Butte mince are being worked continually, by a small force extracting ore. The 1-stamp Sharpneck mill had to shut down several weeks since for want of water, but will soon be running again. The Blue Bird is in fine condition. About 12 miners are employed. The 10 stamps will soon start in motion again. Why this mill ever shut down is a mystery to your correspondent, for it cannot possibly be for want of good paying quartz. The Belmont is now running a full force. Mr. Baldwin, the superintendent, has just finished overhauling and equipping the mine and mill and getting things in the best possible shape for economical working. The Drum Lummon is the same old seven and sixpence. Marysvilliane have given up all hopes of it ever changing owners, until the administrators of Tommy's estate sell the property. Tommy is a pretty tough and hearty old coon now and likely to live many years yet, and they will in all probability have a long time to wait. Placer mining on the creek will soon begin, but most of the placers are owned by the almond-eyed Mongolians; therefore the proceeds do not benefit the "Melican man" much.

NEW MEXICO.

COPPER FLAT.—*New Southwest*, March 25: Considerable work is being done at Copper Flat in the Central City mining district. This camp is about 1½ miles southwest of Woodward's camp. Olvera, Bellm, Barnhizer and Hutchison are all developing their claims. These claims all lie in a basin and are quite rich in copper, and in some cases run some in gold and silver. There are fabulous reports from the Carlisle mine, at Steeple Rock, and Wm. T. Ferrish has undoubtedly added another laurel to his wreath as an expert. The Gila river has been unusually high, and on Tuesday the Clifton coach, and about 20 teams were delayed for a day. The passengers were brought across in Guthrie's private "ceffin," and with the exception of a little leakage everything passed off quietly. Prof. Blake passed through by the Lordeburg coach on his way to examine some mines at Clifton, where he will remain about a week.

TRES HERMANOS.—Meredith & Allman have bonded the Cincinnati mine, in the Tres Hermanos district, for a considerable sum. They have consummated the purchase from D. C. Leroy of the Gen. Hancock and the Toledo mines, an extension of the first. The price for both was $4,000. The bond on the above gives the gentlemen the privilege of doing all the work they please on the mine. They expect to spend $5,000 in finding out the character of the claim. All of the leads consist of carbonate with chloride intermingled. The specimens in the office of Meredith, Allman & Co., which were shown to us, are very rich in horn silver. Two carloads of ore sent to Pueblo, netted Wray, Rascom & Co., the owners of the Cincinnati, at that time, $128 per ton. M. & A. are now timbering the shaft on the Cincinnati, preparatory to working the lead. The crevice of ore body in this mine is about 3 ft wide. These gentlemen will shortly have about 15 men employed on the 2 mines.

OREGON.

GRANT'S PASS.—Jacksonville *Times*, March 31: A Grant's Pass miner writes: Beekman & Klippel will resume operations on the Elizabeth mine in a few weeks. W. A. Johnson has been tunneling all winter and will get out considerable quartz of a promising character this year. Carson & Bybee will commence sinking a shaft on their ledge next month. The long, cold winter has been quite a backset to the miners here, but at the present time we have good weather and plenty of water. Beekman & Johnson's placer mine has been leased for the season to Edward Wade and John Brown. They have sluiced off considerable ground, and are in hopes of making a good clean-up. Wm. Brown is working a gulch claim near the old steam saw mill, with good prospects of fine gold. Fred. Grob, who visited Galle's creek Tuesday, says the miners there have plenty of water and are doing well. The Squaw Lake Co.'s ditch has been cleaned out and put in thorough repair. Piping was commenced a few days ago. The warm weather during the week has been melting the snow in the hills, which is furnishing the miners plenty of water. The Sterling Mining Co. have plenty of water and every pipe is in operation. Supt. Ennis proposes making the gravel fly from now on. Jacob Klippel has received recent advices from T. J. Keaton, now in Idaho, which denote that he is doing well tunneling in Salmon river. Many of the miners will have but a short run this season, on account of the unfavorable winter, but those having ditches or having access to the various streams, will be much more fortunate. Kinney Hammar, of Sterlingville, informs us that the miners of that camp are furnished full heads of water by the melting snow. The same can be said of Foot's creek and other places. W. H. Carter, of Willow Springs, was in town this week looking for hands. His company have several men employed in their mines already, intending to make the best of the opportunity now presented for effective work.

UTAH.

HORN SILVER.—*Southern Utah Times*, April 1: The Horn Silver is not sinking below the 500 level at present on account of not having enough boiler capacity or sufficient cable to sink deeper. We learn that on last Thursday the Frisco Con. Co. had a Government survey made on the Dives mine, with the intention of applying for a U. S. patent. It is the intention of the company to sink down to the deep this summer.

SOUTH HORN.—Work is still in progress on the South Horn under the superintendency of M. L. Cody, and from the thorough overhauling and repairing going on around the mine, he is, we should think, preparing to prosecute work extensively.

LULU.—The drift from the bottom of the 400 ft shaft on the Lulu still continues. A small quantity of water has been struck in this drift which is used for watering horses, etc. A *Times* reporter tasted the water and pronounces it as good, if not better, than the water now used in Frisco.

COMET.—A contract has been let on the Comet tunnel. The face of the tunnel at present shows a good body of ore assaying high in silver and copper. Something of importance will more than likely be shown up in this tunnel, as it is being driven under immense croppings, which it will strike nearly at a right angle.

BINGHAM.—Cor. Salt Lake *Tribune*, April 1st: Bingham, the Old Reliable, is making a good showing and getting out some good ore. The Yosemite is working 20 men, the Jordon 35, the Stewart, No. 1, 30, Osceola, Lucky Boy and the Northern Chief Mining Co. are working a small force. The following mines are leased: Scanlish by A. H. Bemis, working 10 men. He is breaking ground for a 5-stamp mill near the mine. He has a fine body of ore and will make a good clean-up. The Old Telegraph is leased by Hazilgrow & Mullett, who are working 40 men and keep their 5-stamp mill running on good ore. The Winnamuck is leased by 3 different parties, working about 20 men. The Alladin, Neptune, Ashland, Miner's Dream, Victor—Glasgow Mining Co.—are making a good showing. The First West Extension of the Telegraph mine, worked by Lewis Martin, is taking out some fine ore. The Stewart mill, No. 1, is working finely in Carr Fork. The hotel kept by Smith and the Griffin house by A. Klopenstine, are doing a good business.

COAL MINERS' STRIKE.—News from Pittsburg, Pa., dated the 3d, says: The railroad coal operators of the Pittsburg district, according to a resolution passed two weeks ago, reduced the price of mining on Saturday from 4 to 3½ cents per bushel, and to-day 3,000 miners in the Panhandle mines struck against a reduction. A number of the pits are still in operation at 4 cents per bushel, with an understanding that the miners will accept a lower price if the strikers resume at a reduction. The operators claim that they can pay no more than 3½ cents for mining and compete with other districts.

On Minerals.

[Notes of a Lecture delivered before the Mechanics' Institute by A. W. Jackson, Jr., Instructor of Mineralogy, Petrography and Economic Geology, at the University of California.]

(Continued from our issue of March 25th, 1882.)

Cinnabarites.

Tbs chief characteristics of the blendes lie in thsir non-metallic luster and want of opacity. The two sulphides of arsenic (orpiment and realgar) the sulphide of zinc (zincblende); the suh-jarsenide and snlf antimonide of silver (the two ruby silver ores), and the sulphids of mercury (cinnahar), ars the leading members of the family.

Zinchlende, formerly so much drsaded hy silver miners, has quite recsntly become a welcome ore of zinc (through improvement in metallurgical processes).

Ruhy silver I have jnst mentioned as one of ths leading primary silver ores; while cinnabar is too familiar to Californians to need furthsr mention.

Combustibles.

This small class contains the non-mstallic comhustihle suhstances that occur in nature. Aside from the two non-metallic elements, sulphur and carhon, the class is made up entirely of compounds of carhon and hydrogen, or carhon, hydrogen and oxygen. They are compounds that can scarcely be brought under the strict definition of the term "mineral," inasmuch as they are rarely homogeneous, hut rather *mixtures*. There is very little of a general nature to he said of them. I will hriefly mention the leading members of the class.

The familiar suhstance sulphur occnrs very widespread and under a great variety of conditions in nature. It is found in considerahls qnantities in the most recent sedimentary rocks, accompanied hy gypsnm, marl and clay. It is sometimes given off in the form of vapor from volcanoes, condeusing on the crater edges. It is not uncommonly met with on ors veins, and, indeed, is forming in not inconsiderahle quantity at the present time at tbe Sulphur Bank qnicksilver mine in Lake county, Cal. It generally results from the decomposition of sulphydric acid.

Diamond, prized above all other stones sincs 1456, when the art of cutting it first hecame known, as is well known, is the purest form of carbon. It is distingnished in many respects, viz: By its high hardness, hy its hrilliant luster, and by its high index of refraction, which brings about the heautiful play of colors in ths cut stone. It occurs in crystals whicb easily cleave parallel to the faces of the octahedron, hut more commonly still in rounded granules associated often with other gems, like ruhy, sapphire, etc., in placers.

You will find in all the hooks that the rock known as itacolumite, or "flexihle sandstone," is the mother rock of the diamond; that diamonds have heen found in this rock in Brszil.

In spite, however, of the high authority upon which it rests, it would seem as though this statement still needsd confirmation. Prof. Stelzuer, Professor of Geology in the Mining Academy at Freiherg, has told me that, during a stay of ssveral years in South America, he carefully investigated this point; he was not only unahle to find a single specimen of diamond in itacolumite in any of the South American museums, but was also uuahle to find a single persou among those interested that had ever seen such an occurrence. It would seem to furnish a good instancs of the much greater difficulty of eliminating erroneous statements of fact from scientific literature than of making snch statements.

Much more light is certainly being thrown upon the origin of the diamond hy the recent developments in tbe South African diamond fields. It has heeu shown that extensive horizontal beds of hituminous shales havs heen hroken through hy melted rock material from helow. Ths conditions presented, viz.: *Bituminous material* and *heat* from the erupted rock, would seem to be altogether favorable for the formation of the diamond.

The commou form of C., viz., graphite, exists very widely disseminated in rocks of all kinds. It sometimes plays the part of a mica in the crystalline rocks. It is fonnd in largest quantity among the rocks known as the crystalline schists. It occurs in eeveral places in this State, hut alwaye too impnre for use.

The different forms of coal are placed here, although they might with greater justice he considered among the rocks.

Asphaltum and petroleum are the two most important asphaltites or pitches. Both occur in this State, and both are too well known to need further meution.

Amher is the principal fossil form. As is well known, it is the fossilized exudation of a tree, aud is found in the old soil into which it dropped from the tree

Ozocerite is the principal wax. Like most of these hydro-carhons, it is found associated with the softer coals, liguites or hrown coals.

With this mineral we close the rapid review we have taken of the mineral kingdom. We have traveled over a long road in a comparatively ehort time, a road upon which my students spend a whole year instead of an evening. It wae with much hesitation that I attempted to cover eo extensive a field in so short a time. There was danger that I should fail to hold your interest and attentiou on account of the neceesary euperficiality viewed from the standpoint of the individual mineral. Bnt I ehall feel eatisfied if I have eucceeeded in giving you that "Bird's-eye view" of the mineral world, which it was really my object to give.

At my next lecturs I shall attempt to give you some idea of rocks and the rock strncture of the earth, together with a general account of the method of studying rocks. The subject admits of much more satisfactory treatment than the subject of this evening's lecture, inasmuch as the rock types are much fewer in number than the minerals, and they admit of a classification that is to a much greater degree an expression of thsir natural rslations.

Sex in Mineral Veins.

The following curious communication, signed by J. Vau Cleve Phillips, appears in a late issue of the London *Mining Journal:*

In reading Fourier's Philosophy in a nsw hook hy Van Buren Denslow, called "Modern Thinkers," and having read Erasmus Darwin's "Love of the Plants" (Duhlin 1795: grandfather of the present Darwin), I find my idea of sex in mineral veins fortified. My study of ths upper Mississippi lead fisld was from 1844 to 1853, and of the Missouri lead fislds from 1855 to 1880:—1. The lead fields are basins of limestone, these heing from 100 yards to 5 mileswids, and vein system dnplicated in each hasin; 2. All the discovsries of ores in the upper Mississippi and Missouri lsad fisldsmay hs located geograpbically in the hasin where thsy occur, and stratagraphically in the rock and family of veins to which they helong. The lead ores mined in these fields have yielded to date $150,000,000 worth of lead, all of which has heen takeu from the small hasins, or along the edges of the larger ones, aud is from the edge of the vein system, and will not include over 1-20th of 1 per cent. of the ores contained in the basins, as shown in my unpublished geological surveys of the upper and lower Mississippi lead fields. It will he seen from this that the existence of lead and zinc is now known which will supply ths people of the center of the contiusnt with these mstals when it shall have a population of 300 to the squars mile, as England has to-day.

My first attention to ths physical ontline of the crystallization of lead ore was in 1848, while superintending a lead furnacs in Wisconsin. The teams were bringing in ores from 20 different lead discoveries, having north and south veins, east and west veins, and stratified veins from the rock and clay. The east and west veius had regular cubes, the north and sonth veius had the edges of the cubes truncatsd, and the horizontal veius had the solid angles of the tubes cnt off or truncated. Ths ores from ths clay were amorphous, and this form of crystallization was duplicated in each lead hasin. This went to estahlish the fact that ths lead-prodncing and crystallins action had been directly connected with the vein system in all parts of the lead hasin; that the same force which had been exerted to fill the vein system in ons hasin of limestone had dnplicated tbat system in the adjacent hasins, and the physical outlins of the ore was an indsx of its geographical and stratagraphical position in the hasin. Afterwards I was led to the conclusion that the north and south veins were the positive or male veins, and the east and west the negative or female veins. The north and south veins were fsw in number, the east and west veius many, and the north and south veins always pointed towards the hasins of the east and west veins. This law is noticed in the animal and vegetabls kingdoms, in the sheep and goat families, and in the cherry and apple trees, the males being in the minority. In applying this law to iron ores we suppose the magnetic ores are the positivs or male ores, other varisties the negative or female ores. In the silver fields the Comstock, heing a north and soutb vein, would be a positive or male vein, and the east and west veins of New Mexico and old Msxico the negative or female veins.

The great vein known as the San Pietro, in the town of Hidalgo del Parral, is an east and west vein; also the largest and richest mine worked at the old Spanish mining towu of Inde, in the State of Dnrango, Mexico, and known as the Del Aqua (water mine), is an east and west vein. I am not sufficiently acquainted with ths courses of ths veins in the mountain States to apply this law of sex to the vein system of the numerous silver and gold-bearing fields, yet I have identified it in the vein system of the upper and lower lead fields of the basin of the Mississippi, and feel assured that it can he applied to all the families of veins which, as a rule, are aggregated around a central knoh or Boofa, which forms the water-shed of individual families of veins, and which families as aggregated form the great stellar silver helt from Montana south through New and Old Mexico, and that by close observation the explorer and miner may profit hy its application.

The Copper Queen miuing compauy of Arizona has declared its regular monthly dividend of 10 cents per share, or $25,000, payahle at New York on the 1st of April. This company paid au extra dividend of the same amount on the 15th of this month. This is the 11th dividend eince July 1, 1881, when the first was paid. During the past nine months, the ten dividends paid aggregate $250,000. The mine has been a success from the etart, and is represented to he in a hetter coudition to-day than it was niue months ago. It was originally eold to parties in San Francisco, but was suhsequently incorporated under the laws of New York, where the geueral office of the company is located.

The Preservation of Mining Steel Wire Ropes.

Complaints are constantly made as to the rapid wear and tear of stsel wire ropes used for wiuding at mines, and this cannot he said to be owing so much to the quality of the matsrial as to the sudden checking of the movemsnt hy the nse of friction clips when thers is a heavy strain upon the ropes. If checked hy friction, the rope is liahle to heat or tear, or if not allowed to slip at all, to snap off. Now, steel wire ropes are costly things, and should bs mads to last as long as it is possible for them to do, without giving way or breaking, and how this can bs best effected has long been a momentous matter for the consideration of mine owners and mechanical engineers. But no system has been brought forward or adopted until recently by which the full value of a rops can he obtained, and the fraying and breaking of the strands effectually prevented. An invsntion, however, has recently beeu patented in London, and is described in the *Mining Journal*, which promises to be of considsrable value. The invention is patented by Mr. R. B. Jones, of the firm of Garnock, Bihhy & Co., of Liverpool, and James Hughss, an employee of the firm, and relates to improvements to clips, stoppers, or brakes for steel wire and other ropss, being also applicable as winches or for hauling purposes, so that a hrief notics of the iuvention must he of more than ordinary interest to those daily nsing metallic ropes. The invsntion is designed to check the rops whilst working, without any of the severe punishment caused by hard compression or attrition, end without sensihle wearing friction on the rope. For this purpose a brake is fixed, not the rope itself hut on mechanism connected with V-pulleys, rouud which ths rope is twined forming a figure of eight. The friction on the pullsys is so great by reason of ths tnrn round each pulley given to the rope that no appreciahls rslative motion can take place between the pullsys aud the rope. As a hrake, however, is applied on the axles of ths pulleys, or rather on brake wheels on these or on one of tbe axles, whatever friction is expended ou stopping the rope is spent on the brake-block or the belt and brake-wheel and not on the rope. The apparatus is simple and effectual. Upon the overhanging snds of two shafts having hearings in a stout frame fonr pulleys are placed, two on each shaft, which are connected by spur gearing. On the other euds of the shafts are placed two hraks-wbeels with a singls brake-strap, so arranged that a man, by means of a levsr, can put a snfficiently powerful strain ou the brake-strap so as to give the hreks ths requisits power.

Upon one of the shafts is a worm wheel, or first wheel of other train of gearing, and a clutch, so arrangsd that the gearing can be thrown into gear with the shaft at a moment's notics aud hs thrown out again, and ths gearing can be worked either hy hand or power. In operation the rops is passed from a resl through a guiding eye ou to one of the other pulleys; it passes round that, theu ronnd ths othsr outer pulley the opposits way, then round the opposits innsr pulley, the direction heing the same as in the first instance; and, lastly, it goss round tbe remaining pulley in the same direction as round its companion second pulley. The brake can hs applied gradually or suddsnly without any more friction or severe compression on ths rope. By putting the clutch into gear the apparatns becomes a wincb, and, the hrake heing thrown out of action, the rops hauled in. In lowering heavy wsights the hrake can be applied, ths clutch thrown out of gear, and the descent rsgulated with the greatest nicety hy hand pressure on ths brake levsr. Ths apparatus is no more severe on the rope when the hrake is applied than at other times, excepting, of course, the increased tensile strain necessarily entailed when ths lowering of a heavy wsight is chscked, and whilst in othsr winding apparatus thsrs is ths riding of one turn over the other to the great injnry of the rops, in the Jones and Hughes apparatus the drum can be colled to any depth hut no turn rides ou the other under pressurs from the strain of the work performed. The apparatus can also bs used merely as a stopper or hrake, or a winch, as they may be desired; so if the winch he not required the spur wheels and winch need not he added, and it becomes a simple stopper. This simple machinery, so admirably adapted for clipping, stopping, hauliug, or hraking still wire ropes, and can be so easily arranged as to make a complete winch or stopper, should commend itself to mine owners as well calculated to preserve the ropes for winding, and so ohtain from them a much larger amount of work than is now the case.

To Find the Size of Rail Needed for a Locomotive.—Multiply the number of tons (of 2,000 lbs.) on one driving wheel by 10, and the result is the nnmher of pounds per yard of the lightest iron rail practicahle. This rule is only approximate, and is suhject to modification in practice. (Note.—If, as is usually the case with four-wheel-connected locomotives, the weight ou front aud back driving wheels is not the same, the heavier weight must be taken.)

A New Mining Chair.—A fellowship in miniug has been estahlished at Prineeton, which is to he opeu to the seuior clase and to post-graduate students. The income of the fellowship is $600, and the fellow will be required to spend one year in the continuous etudy of the minee aud miuing interests of Colorado. The first award will he made on examiuation next Juue.

Secret Canyon.

Mines in the Baee Range.

The following letter, by John M. Folsy, appears in the Eureka *Sentinel*: Notwithstauding the many ohstacles that have impeded the progress of this slighted and nsglected end of tbe Base range, Secret Canyon mining district is raddidly coming to the front. The great Salishury mill is fast nearing completion. Not knowing anything about machinery, I cannot express an opinion of its msrits or dsmsrits; but this I do know, that Secret canyon contains within itself the elements that guarantees its futurs prosperity. Capital is taking a hold, mines are being incorporatsd, new ones are bsing discoversd, an embryo town is started, many tunnels ere beiug run to tap the mothsr lode, and a general confidence has of lats been inspired. The fact of this mining district being situated so near to the cslehrated and far-famed Eureka district may, in a msasure, account for the incredulity and skspticism so often expressed in regard to the extent and value of its mines. Secret canyon is to-day as if a pound of ore had nsver been extracted from its mines, almost in a virgin state, for the work tbat has been going on bers for tbs ysars psst is surface work—mere scratching. The ores to he fonnd here are dsep.

Now, deep tunnels are hsing run to tap the contact vein. Whsn this is done a graud destiny awaits this district. It will becoms one of the great camps of the State. Nothing can stop it, for the reason that mines and wealtb ars here. The southern end of Prospect mountain extsnds through the district and contains the chisf lode, ores from which have heen extracted that throw Ruby hill and the north end of the mountain in ths shade. A prospector standing ou tbe summit of War Eagls mountain, ths highest in this district, sees the rounded foothills and deeply erodsd canyons which tell him that the landscaps nnder his feet is a patchwork of many rock groups, tbs principal heing sedimentary, through which some of ths oldest eruptive rocks crop out. Geology clearly demonstrates the fact that this part of the earth's surface was for ages covered by the sea. The next geologic event after the birth of those mountains was the pouring out of an immense sea of molten rock, flowing north and south as a sea of firs. Upon the highsr elevations it cooled under the atmosphers and formsd a compact porphyritic rock, while down on tbe lower levels it cooled under water and formed a loose tufaceous rock, now used as the building stone fouud in the quarriss around Eureka, aud extending from there far bsyond this place to the south. A succession of eveuts reaching back throngh geologic time is registsred in the rocks that encass the mother lode of this district—he one born of fire or igneons and the othsr formed of sedimsnt under the sea. Under the atmosphere the world is forsver wasting away. Under the sea it is forever building anew.

The Geddes & Bertrand, for whoss development much money is heing spent in constrncting a great mill and improved machinery, is on this lode, with many other miues equally as great, but too numerous at the preseut time for msntion in this article. The Irish Embassador, the first in richness of the silver deposits of this part of the State, is a fissure vein located on tbs mother lode. The hills here culminate in War Eagle mountain, which is 9,500 ft. ahove tbe sea lsvsl. Ths elsvation of ths range is considsrably lower as it approaches Austin hill. On the soutb side, and ahout 600 ft. in elevation ahove the Bassy canyon, are fouud ths croppings of ths Irish Embassador mine, the general course of which is E. N. E. and W. S. W. The veiu stone projects above the general contour of the hills in a fsw places, hut the greater part of its length is hidden under heavy masses of dolomite and porphyry. Ths slope of the hill varies from 25° to 35°, and ths dip of the lode is nearly 40° to the N. N. W.

Upon entering the mine, on the first level, more than 100 ft. helow the snrface, we find ourselves immediately in ore. The main shaft, inclined, is 4½x6 ft., and 250 ft. in depth, and contains ors from top to hottom. The first level has a track 50 ft. in length, and an upraise 40 ft. toward the surface, from hoth of which a quantity of rich ore was sxtracted. Upon descending the main shaft from tbis lsvel the ore body rests on a smooth foot-wall of silicious limestone and dips all the way to the lowest workings, at an angle of 38°. On the second level a drift rnns west hy southwest 60 ft. in rich ore, much of which worke $800 to the ton. At the end of this drift a winze is eunk 40 ft. in rich ore. From the hottom of tbis winze another drift is run west hy southwest 47 ft. in ore, some of which will assay very high. The third level has a drift runniug east by north-eaet with three ft. of rich ore, every pound of which will assay into the thousands. In this drift, as the work progresses, the ore-body increases in size. From this level another drift is run 40 ft. west by eouthwest, coutaiuing ore of the eame quality as in the east drift. Tbere are other workings too numerous to mention, containing ore of the same character and quality.

This mine reflects credit on its capahle foreman, from the fine manner in which it is opened up. The workings aggregate 600 feet of drifts, winzes and upraises, and must have cost a large sum, as the rock encountered was a very hard silicious limestone. But the mine is ahle to etand it, as ore is found everywhere all through the workings. There is a large amount of very rich ore sacked on the different levels to be taken out when the snow is goue. Foul air hae

retarded the developments. A furnace has been built, and pipes have been run down to the lowest workings for ventilation. In one part of this mine the working forces of matter are playing an important part—that is, chemical, electrical, magnetic and mechanical forces blend in a harmonious manner in forming a mass of crystallized quartz, that will eventually lead to another large body of ore. A deep tunnel is about being driven to tap the mine 500 feet in depth. When this is done the Irish Embassador will be the richest, as well as one of the greatest, ore-producing mines of the State.

U. S. Engineering in California.

The telegraph from Washington announces that Colonel G. H. Mendell's final report upon his project to protect the navigable waters of California against the effects of hydraulic mining has been printed with unusual promptness, and advance copies were received by the House Committee on Commerce, to-day, in accordance with an arrangement made by the chairman (Mr. Page), who intends to bring the subject up for consideration at the earliest possible period, with a view to having an appropriation for this purpose inserted in the annual River and Harbor Appropriation bill. Mr. Page is confident that the committee will act upon the proposition favorably, and that an adequate appropriation for beginning the work will be provided by Congress during the present session. Colonel Mendell's recommendations in regard to California rivers contemplate the construction of a dam on Yuba river, at the narrows, of a height of 75 ft., to cost $204,779; and for repairing brush dams, $80,000. He recommends that $113,500 be expended the first year on the works. He recommends the erection of a dam along Bear river of a hight of 34 ft., to cost $24,600, of which $15,000 should be expended the first year. On the American river he recommends the building of a north fork dam, to cost $24,600, and a middle fork dam, to cost $81,900, of which $22,150 should be expended during the first year. The whole recommendation involves an outlay of $511,600, which is to be expended in 10 years.

Fuel for Smelting.—The cost of wood at Tombstone for milling purposes has risen to $12 per cord with a scant and fast decreasing source of supply—and the mill men of southern Arizona are looking towards the coal deposits of New Mexico for their future supplies. Northern Arizona is exceptionally fortunate in having so great an abundance of timber contiguous to its mining camps, and the price of fuel hereabouts does not in many cases exceed from $3 to $3 50 per cord. It will take a long period of activity in mining to so reduce our resources of wood as to increase the prices much beyond the figures given, and the near proximity of an inexhaustible coal field insures us cheap fuel for all time to come. It is asserted with much confidence by the proprietors of recent English patents that the sulphur in certain classes of ores can be utilized alone for the purpose of smelting the ores with which it is associated, so that even without either wood or coal there is a large and economical fuel supply in many mines in this section if we are to believe the glowing accounts of this process given us by the leading foreign mining journals.—*Prescott Courier.*

Yosemite Valley.—The Yosemite Valley Commission met on Monday afternoon, and decided to purchase the Glacier Point trail, and make it free to the traveling public. A communication has been received stating there is nearly five ft. of snow in the valley, and that the wind has made severe havoc among the trees in one spot, just immediately under Glacier point. Large pines and cedars, from two to four ft. in diameter, have been broken off like pipe-stems; others were uprooted. Large limbs have been wrenched off and hurled into and across the road. Destructive as this wind was, it has opened up one clear spot for the better view of the grand wall of Glacier point, leaving timber and firewood for the valley's use. The mail carrier reports from 12 to 15 ft. of snow on the mountains, so that the falls will be exceeding grand this spring and summer.

Vanadium.—The Prescott (Arizona) *Courier* says: We learn from Mr. C. A. Behm that ore from Ed. Farley's vanadium mine, near Wickenburg, is selling at $4 per pound, and that arrangements are to be speedily made for working it by machinery. We confess to not knowing the utilitarian application of this metal, which is said to be worth, in a pure state, more than $2,500 per pound. Prof. Silliman states that it occurs more plentifully in some Arizona mines than in any other hitherto prospected source. It is found in some of the mines of Silver district, and is described as occurring in crystals of color varying from deep to light orange, somewhat resembling bichromate of potash, and scarcely distinguishable from chromate of lead.

The Michigan Legislature has summarily refused to subject church property to taxation, but the subject is likely to be considered in Ohio. The value of this property in the country is now estimated at over $600,000,000, and nowhere is it taxed.

The preparations for increasing the production of petroleum in the Pico district, Los Angeles, are on an extended scale. New wells are being sunk with great dispatch.

Useful Information.

Wood Acid.

An important industry is growing up in the manufacture of pyroligneous acid, or wood vinegar, distilled from woody fiber. The harder kinds of wood are used for this purpose, such as oak, birch, beech and maple. The distillation takes place in closed retorts, by means of a heat gradually raised to low redness. The country along the line of the Ontario and Western railroad, in Delaware and Sullivan counties, N. Y., is occupied by manufactories of this article, for the vast growth of hard wood in that section of the State is as essential to this business, as a bark supply is to a tannery, or logs to a sawmill. A dozen factories are now in operation in the two counties named, and several more are to be started. For years the secret of manufacture was kept from the public, as those in the business chose to make a monopoly of it, and keep up the prices as long as possible. The products of the factories are alcohol, or naptha, charcoal, and ashes. The acid, when ready for market in barrels, is a dry, dark-colored substance, in small pieces, and looks about like hickory bark if broken into pieces. In an estimate of the weekly business and profits, the books run thus: Cost of wood, $140; six men, $45; lime, $10; cartage, $10; interest and wear and tear, $15. Total, $220. Credit with five barrels of alcohol sold, $260; the weekly sale of charcoal, $40; five tons of acetate, $360; ashes, $12.50. Total, $862.50, showing a net profit weekly of $642.50. Owners are inclined to exaggerate the cost of factories, representing it all the way from $20,000 to $30,000. Five or six thousand dollars is about the figure.

How False Teeth are Made.—A reporter of the Wilmington (Del.) *Star* recently visited a factory where false teeth are made by the million. In the process of manufacture the silex and feldspar in their crude state are submitted to a red heat, and then suddenly thrown into cold water, the effect being to render them more easily pulverized. Having been ground very fine in water, and the water evaporated, the two materials mentioned are dried and sifted. The kaolin is washed free from impurities. These materials, with feldspar, sponge, platina and flux, in proper proportion for the enamel, are mixed with water and worked into masses resembling putty. This done, the unbaked porcelain masses are ready for the molding room. The moulds are in two pieces, and made of brass, one-half of the teeth or sections being on either side. The coloring materials are first placed in the exact position and quantity required, and the body of the tooth and gum is inserted in lumps corresponding to the size of the teeth. The moulds are then closed, and they are dried by a slow heat. When perfectly dry they are taken out and sent to the trimmer's room. The trimmers remove imperfections, and send them in trays of fire-clay to the furnace, where, having remained for 20 minutes, they are complete.

Improvements in Glass Manufacture.—It has long been the aim of those interested in glass manufacture to devise some means by which a perfectly colorless glass could be produced, and it is within bounds to say that very large amounts of money have been expended in experiments having this end in view. While some practical good has been accomplished in improving the quality of the vitreous product, all experiments have thus far fallen short of the desired results. Papers have been recently filed at Washington for a patent for a new process of glass manufacture, the inventor claiming to be able to produce colorless glass, or glass of any color or shade of color desired, and that he can do this with any glass-making plant now in use, no modification of existing melting furnaces being necessary. The product, according to the papers filed, is free from striæ and other imperfections common to glass made by the ordinary process, as well as stronger and better in other respects. If the inventor has actually accomplished what he claims to have done, he certainly has a fortune within his grasp. It is said that experiments are about to be made in Pittsburg to give the invention a practical test.

A New Variety of Glass.—A Vienna chemist has recently discovered what he claims to be a new variety of glass. It does not contain any silica, boric acid, potash, soda, lime, or lead, and is likely to attract the attention of all professional persons on account of its peculiar composition. Externally it is exactly similar to glass, but its luster is higher and it has a greater refraction, of equal hardness, perfectly white, clear, transparent, can be ground and polished, completely insoluble in water, neutral, and it is only attacked by hydrochloric or nitric acid, and is not affected by hydrofluoric acid. It is easily fusible in the flame of a candle, and can be made of any color. Its most important property is that it can be readily fused on to zinc, brass and iron. It can also be used for the glazing of articles of glass and porcelain. As hydrofluoric acid has no effect on the glass it is likely to find employment for many technical purposes.

Luminous paint is now being utilized for door plates, house numbers and signs. The advantages are obvious.

A New Manganese Mineral.—On the McDonnell claim, in Hall valley, Park county, Colorado, 13 miles from Webster, a new mineral has been found, which is described at length in the *American Chemical Journal* by Dr. Malvern W. Iles, of the Grant smelting works, Leadville. A number of analytical determinations show it contains zinc, iron and manganese. The analyses lead to the formula $FeO, SO_3.FeO,SO_3.5Mn,OSO_3.+2HO$; density, 2.1; hardness, 0.75 to 1.; color, milky white; soluble even in cold water.

The Ancient Sawmill.—This is how they used water power to saw wood in England 300 years ago: "The sawmill is driven with an upright wheel, and the water that maketh it go is gathered whole into a narrow trough, which delivereth the same water to the wheels. This wheel hath a piece of timber put to the axle-tree end, like the handle of a broch, and fastened to the end of the saw, which, being turned with the force of water, hoisteth up and down the saw, that it continually eateth in, and the handle of the saw is kept in a rigall of wood from swerving. Also the timber lieth as it were upon a ladder which is brought by little to the saw with another vise."

False Eyelashes.—Labouchere says in *Truth*: "The Parisians have found out how to make false eyelashes. I do not speak of the vulgar and well-known trick of darkening the rim round the eye with all kinds of dirty compositions, or the more artistic plan of doing so to the inside of the lid. No, they actually draw a fine needle, threaded with dark hair, through the skin of the eyelid, forming long loops, and after the process is over—I am told it is a painless one—a splendid dark fringe veils the coquette's eyes."

Dynamite.—It is said that the 15 dynamite manufactories now under the control of M. Noble (the man who introduced nitro-glycerine in its varied forms into public use), turn out about 5,000 tons a year. In this country and in Europe it is estimated that the production of explosives containing nitro-glycerine is between 7,000 and 8,000 tons a year, and this quantity has the energy of at least 45,000 tons of ordinary gunpowder.

Special poisons are secreted by the toad, salamander, newt, frog, etc. M. Paul Bert has collected a liquid from the glands on the neck of the frog which caused the death, with convulsions, of a sparrow to which the substance had been administered.

Good Health.

Keeping Warm.

Dyspeptic persons, those having feeble digestion or a poor appetite, get less internal heat from food combustion, and suffer from cold. Such persons need a warmer atmosphere or warmer dwellings, and warmer clothing to retain the heat that is produced. This applies to all animals.

Close-fitting garments, garters, lacing, boots, shoes, neckties, etc., that prevent free, easy circulation of the blood, each and all diminish the amount of heat produced and its uniform distribution. Exercise promotes more rapid circulation of the blood and increased heat production.

Rubbing wet horses and other animals dry is very useful, not only to save heat, but also to save cold taking. For the same reason any damp garments should be replaced with dry ones as soon as possible, or enough covering be added to prevent chilliness from the evaporation.

Free perspiration (sweating) in hot weather carries off a large amount of heat, and keeps down the temperature. If perspiration be checked, sponging with water aide in cases of sun-stroke or depression from heat. Persons have gone into hot ovens unharmed by encasing themselves in moistened garments, the evaporation keeping down the heat about the body. Green wood, besides its inconvenience, is very unprofitable. A large amount of heat which the dry portions would yield is lost by being carried off in the evaporation of the sap. So of any wet or damp fuel of any kind.

As confined air is a poor conductor of heat, all fabrics that are porous, that is, full of little interstices, tubes or holes filled with air, are the best protectors to keep heat from escaping from the surface of the body. A loosely-worn garment or bed coverlid, is warmer than a compact, firmly woven one, because the air in the texture of the former conducts away heat less rapidly than the solid ones. Loose-fitting garments are warmer than close-fitting ones, for reasons above given, and also because the air-space between them and the skin is a non-conductor of heat.

Stone, brick or wooden walls, with perpendicular air-spaces in them are warmer than solid walls, because the air conducts the heat away less than the solid materials. A sheathing of tarred paper, or pasteboard, or of any thick paper, even, placed midway between the clapboarding and the plastering to form two thin air-chambers instead of one, adds greatly to the warmth of a house or other building. Two half-inch boards set a little apart to leave an air-space between, make a far warmer house-wall than the same thickness of wood in inch boards.

A layer of loose straw put between the wall and the earth banking up of a cellar adds much to the warmth, on account of the air in the meshes of the straw. The same is true in covering roots or apples to be left out in heaps over winter.

Double glass windows are several times warmer than single glass, because of the non-conducting film of air between. So of double doors.

Moving air both carries off heat faster of itself and also increases evaporation, thus largely diminishing the temperature. A very small crack in a window, under or over, or by the side of a door or sash, or elsewhere, produces a draft that requires much extra fuel to counteract the effects.

Sheltering all animals from the cold weather, from chilling winds, which by their motion carry off heat more rapidly, is the way to save food and to save waste of flesh. If by stopping this waste of heat from the surface, all the food consumed will not be wanted to make heat, a portion of it can go to increasing the flesh; that is, to producing growth, or more can be used in making milk, eggs, etc., within the animal.

Vaccination for Splenetic Fever.

Louis Pasteur, the distinguished French chemist and author of "Researches in the Direction of the Germs as the Origin of Disease," is still continuing his work. His latest contribution on "The Germ Theory" is to the *Popular Science Monthly* for April, from which we extract as follows: "The method I have just explained of obtaining the vaccine of splenic fever was no sooner made known than it was very extensively employed to prevent the splenic affection. In France we lose every year by splenic fever animals of the value of 20,000,000 francs. I was asked to give a public demonstration of the results already mentioned. This experiment I may relate in a few words. Fifty sheep were placed at my disposition, of which 25 were vaccinated. A fortnight afterward the 50 sheep were inoculated with the most virulent anthracoid microbe. The 25 vaccinated sheep resisted the infection; the 25 unvaccinated died of splenic fever within 50 hours. Since that time my energies have been taxed to meet the demands of farmers for supplies of this vaccine. In the space of 15 days we have vaccinated, in the departments surrounding Paris, more than 20,000 sheep and a large number of cattle and horses. If I were not pressed for time I should bring to your notice two other kinds of virus attenuated by similar means. These experiments will be communicated bye-and-bye to the public. I can not conclude, gentlemen, without expressing the great pleasure I feel at the thought that it is as a member of an international medical congress, assembled in England, that I make known the most recent results of vaccination upon a disease more terrible, perhaps, for domestic animals than small-pox is for man. I have given to vaccination an extension which science, I hope, will accept as a homage paid to the merit and to the immense services rendered by one of the greatest men of England, Jenner."

Cutting New Teeth at Ninety-five.—Elias de Puy is 95 years of age and still able to walk eight miles a day over rough hills. He lives near Lackawack, in Ulster county, N. Y., in a country sparsely settled, on rough farming lands. He is in excellent health, yet not a follower of temperance principles, for he believed in the old Dutch custom of taking gin "straight," and has chewed all his life the rankest and strongest tobacco. He has had five wives and eight children. His eldest son is 70 and gray-haired, while his youngest son was born after he was 85 years old. He was 60 years of age when he married his last wife, while she was 19. A remarkable thing about Mr. de Puy is that he is cutting a new set of teeth. Nine new teeth have already made their appearance. His eyesight is excellent, and he reads almost continually. He is the most remarkably preserved man in the State.

Remarkable Brain Wound.—A young man named Leonard E. Spencer, of North Fenton, Broome county, N. Y., was wounded in the head October 8, 1881, by the bursting of his gun. His physicians were able to insert a finger its full length into the wound, but were unable to find the fragment of the gun which penetrated the brain. Partial recovery took place. He was at work February 20, when unfavorable symptoms set in, and he died the next day. At the autopsy the cylinder and tube of the gun were found embedded in the brain, near the fore part of the skull. The cylinder and tube were connected in one piece and weighed about three quarters of an ounce. The patient had survived the injury four and a half months.

Sea Bathing Good for the Eyes.—Dr. Amat says that sea bathing "has proved of great benefit in many cases of disease of the eye. The improvement appears to be due to two causes: 1. The influence which such a course has upon the general health, by curing anæmia and elevating the tone of the system, since sea bathing is in the highest degree restorative. 2. Sea water and occasionally, also, the atmosphere of the sea has a local irritant action which should be watched, since it is most serviceable when there is a chronic, torpid and indolent inflammation, while it is exceedingly dangerous when the inflammation is of the acute kind."

SAN FRANCISCO:

Saturday Morning, April 8, 1882.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—New Dry Ore Separator; Sluice Pavement; A Generous Gift to Science, 225; Passing Events; Oaths by Proxy in Mining Cases; New Hurdy Gurdy Water Wheel; Sanitary Science, 232. The San Gabriel Mission, 233.

ILLUSTRATIONS.—Bourne's Dry Ore Separator; Pavement for Mining Sluices, 225. San Gabriel Mission, 233.

CORRESPONDENCE.—Snow Perils of the Upper Sierras; Alpine County Mines; Antimony Mine, 226

MECHANICAL PROGRESS.—Lubrication; Progress in Machine Construction; The Pro and Con of Brakes. 227.

SCIENTIFIC PROGRESS.—Respiration in the Mammalia; Relation of Atmospheric Resistance to Temperature; Effects of High Barometric Pressure, The Expanding Power of Ice; Mental Distance of the Moon; Improved Lenses for Telescopes, 227.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Assessments, Meetings and Dividends, 230.

MINING SUMMARY from the various counties of California, Nevada, Arizona, Montana, New Mexico, Idaho, Oregon, and Utah, 229-30.

USEFUL INFORMATION.—Wood Acid; How False Teeth are Made; Improvements in Glass Manufacture; A New Variety of Glass; A New Manganese Mineral; The Ancient Sawmill; False Eyelashes, 231.

GOOD HEALTH.—Keeping Warm; Vaccination for Splenetic Fever; Cutting New Teeth at Ninety-Five; Remarkable Brain Wound; Sea Bathing Good for the Eyes, 231.

MISCELLANEOUS.—On Minerals; Sex in Mineral Veins; The Preservation of Mining Steel Wire Ropes; Secret Canyon, 280. U. S. Engineering in California, 231.

Business Announcements.

Tonite Powder, Tonite Powder Company, S. F.
Chemical Stoneware, R. C. Remmey, Philadelphia, Pa.
Dividend Notice, Standard Con. Mining Company, S. F.
Ore Concentrators For Sale, No. 73 Nevada Block, S. F.

Passing Events.

The topic of the week has been the very unwelcome veto of the Chinese bill, news of which, though not unexpected, was received with sorrow and indignation by all classes on this coast. All good citizens must deplore the fact that these people will continue to displace white artizans and laborers, to the great detriment and retardation of all home industries and the growth of the State. Progressive industrial classes will not come to us to be brought into competition with the Mongolian.

As will be seen by what is said elsewhere, a meeting of mining men has been held, to devise means of draining the flooded mines of the Gold Hill section of the Comstock. Mr. Patton presented figures showing the amount of water to be pumped out, and estimated the cost of the work at about $500,000. This is a matter of very great interest.

Lead and copper ores are now in great demand, and prospectors will pay more attention to them than has heretofore been the case.

In another column is noted the very generous gift to science of Messrs. Leland Stanford and Chas. Crocker, who presented the Ward collection of fossils, minerals, etc, now in this city, to the California Academy of Sciences.

FOUNDRY AT TOMBSTONE.—James McAllister has bought the Tombstone foundry and machine-shop, and will take possession on Monday. A large part of the iron-working machinery now in the Union foundry, in Virginia City, Nevada, will be removed to this place, thus making this the biggest iron works south of San Francisco.—*Epitaph.*

Oaths by Proxy in Mining Cases.

The Senate has passed the bill introduced by Senator Hill, of Colorado, to allow adverse mining claimants to make necessary affidavits by authorized agents in a local district, or else before the clerk of any Court of Record. The present law, as construed by the Interior Department, requires oaths to be made in person, and in the districts where the claims are situated.

It seems to us that there is now altogether too much opportunity for loose swearing in mining cases without making it practically legal to make oath or affidavit by proxy. It is already understood that one may locate claims without being within a thousand miles of them; and this gives people a chance to appear by an agent in a matter which may, without putting them to any expense, delay and hinder parties who want to patent their claims previous to selling.

A New York man can now locate a claim in Colorado or California, and can appear (by proxy) and prevent others patenting their claims, without leaving home. This is open to several forcible objections.

It was, some years ago, officially decided in a Nevada court, in the case of the 420 Mining Co. against the Bullion Co., that the object of the acts of Congress, in relation to the patenting of mining claims, was not to confer any additional jurisdiction upon the State courts, but to require parties protesting against the issuance of a patent to try the right of possession and have the controversy determined in the State courts, by the same rules, and governed by the same principles, and controlled by the same statutes that apply in other cases.

It was decided by the Honorable Secretary of the Interior, on Nov. 24, 1873, in the case of the Jenny Lind against the Eureka, that an adverse claim, to be considered, must be sworn to by the party claiming adversely, and *not* by an attorney. This ruling has been enforced by the Commissioner of the General Land Office.

The Secretary of the Interior, in an appeal case, in 1874, would not recognize an adverse claim because it was not sworn to before an officer authorized to administer oaths in the land district in which the claim was located. It was decided, also, by the Secretary of the Interior, in 1873, that a commissioner of deeds for Nevada, residing in California, was not an officer before whom an adverse claimant to a mine in Nevada might make oath to his claim.

It has been decided long since, and the ruling maintained by the Commissioner of the General Land Office, that an adverse claim cannot be filed by a party having no interest.

All these rulings are now overturned by the new procedure, simply, it appears to us, for the convenience of a lot of "stay-at-homes," who will act as blocks to the progress of every mining camp.

It is provided in Sec. 2326 of the U. S. revised statutes, that the adverse claim shall be filed during the period of publication of notice; that it must be on the oath of the adverse claimant, and that it must show the nature, the boundaries and extent of the adverse claim.

To carry this section of the law into effect, the Land Office instructs that the adverse notice must be duly sworn to by the person or persons making the same, before an officer authorized to administer oaths within the land district, or before the registrar or receiver; it will fully set forth the nature and extent of the interference or contest; whether the adverse party claims as a purchaser for valuable consideration, or as a locator; if the former, a certified copy of the original location, the original conveyance, a duly certified copy thereof, or an abstract of title from the office of the proper recorder should be furnished; or, if the transaction was a mere verbal one, he will narrate the circumstances attending the purchase—the date, the amount paid—the facts to be supported by witnesses, if any; and if he claims as a locator, a certified copy of the location notice must be filed. He must file a plat showing his entire claim and its relative position to the one against which he claims, and the extent of the conflict. This plat must be certified, and show shafts, tunnels, etc.

Under this new law, all this can be done by any person paid to represent the adverse claimant, the latter individual remaining quietly at home. This is all very well for the rich man, but will work hardship on the poor one.

It is of course possible, under these circumstances, for unscrupulous men to actually "freeze out" legitimate owners, by getting equally unscrupulous men to file adverse claims. The original owners, by delay, hindrance and expense, will compromise or do anything to get rid of the burden. True, the Secretary of the Interior has disregarded an adverse claim, because supported only by affidavit, but in the very decision which establishes this rule, he officially admits that the mere affidavit, unsupported by other proof, *delayed* the case for the period of over a year.

A man is compelled by law to advertise for a certain period that he is going to apply for a patent for his claim. This gives people a chance to file adverse claims, as it is intended to do; but it also gives people a chance to annoy claimants, and, in some cases, levy blackmail, or what is equivalent to it.

It was officially decided by the Land Office, in 1874, in the case of the Shoo-Fly, Magnolia and others against Mono, that any state of facts which shows that the person alleging the same has a better right to the premises sought to be patented, or any portion thereof, than the applicant for patent, is the proper subject-matter of an adverse claim, and when properly set forth, should be treated as such. Under this ruling and subsequent ones, it is possible for people not legitimate adverse claimants to annoy the applicants for patent exceedingly.

New Hurdy-Gurdy Water-Wheel.

In no place in the world are "hurdy-gurdy" water-wheels, as they are called, so commonly in use as on this coast. Since the early miners first began to use this form of wheel it has been much improved. In wheels of this character, revolving in a vertical plane upon a horizontal axis, the nozzle from which the water is forced is usually placed at the lowest position of the wheel, so that its stream may be directed upon or into the buckets descending as they successively come within the line of its discharge. These buckets upon the rim are generally placed so close together and the nozzle in such near proximity that a prime object is to construct them so that they will free themselves of the water the moment its force is expended, in order that they may not interfere with each other and retard the wheel.

In the first forms of these wheels, perfectly flat pieces were used, against which to direct the stream. These, while they were of a shape to receive the force of the stream to the best advantage, could not easily free themselves, and the water having no proper reaction, remained to hinder the succeeding buckets, and the progress of the whole wheel. An attempt was made to improve upon this by inclining the edges or sides of the buckets, the bottom still remaining straight and flat, and though this effected good results, it still failed to free the buckets. Subsequently, a scoop-shaped bucket was introduced, the inner face of which was bounded entirely by curved lines. This bucket freed itself by the reaction of the water much better than the others.

Daniel Donnelly, of Sutter Creek, California, has just patented, through the MINING AND SCIENTIFIC PRESS Patent Agency, an improvement in this class of wheels. He thinks, in relation to the scoop-shaped buckets, thus far considered the best, that the force of the water is impaired by striking upon or within a complete concavity; and whatever advantage the first forms of buckets possessed by reason of opposing a flat surface to the stream was thus destroyed. Another objection he makes to all the forms of buckets used in this connection is, that their backs are so formed as to carry up water with them, thus, in a measure, retarding the motion.

In the improved buckets devised by Mr. Donnelly, and which form the subject of his patent, each has at its rear end a shank, set a little off the center, and they are fitted to the rim of the wheel by having their backs impinge on its periphery and their shanks pass beside it, and bolted or riveted thereto securely.

The shape of the face or inner surface of the bucket may be thus described: In the direction of its length—that is, from top to bottom—it is hollowed out, its walls sloping in curved lines to the center. In the direction of its width—that is, from side to side—it is hollowed out down to a certain distance upon each side of a central line drawn through its length, and is then left flat. The flat portion extends the length of the bucket, and may be in width about one-third of the whole, or sufficient only to receive upon itself the stream of water. The bucket being hollowed out in this manner, the edges are curved down, those upon the sides in a true curve, while those upon the ends are curved down to a straight line.

The stream strikes the face of the bucket below the center upon the flattened portion, which presents a better surface for the impact, the inventor thinks, than if it were concave on all sides. After striking it follows easily the contour of the curved sides, rather than the flat portion, and is discharged from side to side, rather than over its top and bottom. Thus the inventor obtains the advantage of a flat or straight surface against which to direct the water and at the same time he has the curved sides, which free the buckets in the reaction.

In order to be impeded as little as possible by the spray and waste water, the outer or back surface of the bucket is constructed in lines that are all curved or sharpened to an inclined line in the center of the back, in a manner similar to the prow of a ship. This adapts it to clear itself of water readily, very little being carried up with it, and the inventor is confident that this is a very decided point of advantage when the wheel is revolved at a high rate of speed.

CABABI DISTRICT.—The Arizona *Citizen* says: Mr. David Armstrong left the city this morning for the Oro Plata mines, Cababi district. These mines have recently been incorporated. Mr. Armstrong as superintendent will commence active work on the property at once and goes for the purpose of letting contracts on the different claims. Considerable work has been done on the Copperopolis mine, and from the showing of a shaft which is now down over 50 ft. has the promise of something unusually rich for its lucky owners.

Sanitary Science.

An Inquiry Into the Cause of the Abnormal Death Rate in San Francisco.

EDITORS PRESS:—The recent inquiry into the causes of the abnormal death rate, has brought to public notice the execrable blunders of the engineer and builders and the present horrible condition of our sewers, and it is to be hoped that it may lead to beneficial results.

While it is admitted by all that the sewers are very defective in construction, and in certain places entirely inoperative, and while there is no question as to the insanitary character of sewer-gas, nor as to its deleterious effects, particularly when it gains access to our houses, there is room for doubting and antagonizing the theory so persistently urged by certain experts and supervisors, as reported in some of the public journals, that "there is no other way of accounting for the recent weekly deaths ranging from 125 to 135."

Without calling in question the motives of these alarmists, let us look closely at this subject in the light of sanitary science and our own experience, and we shall probably discover that "the extraordinary mortality this winter" should *not* all be laid on the bad sewers.

The measures recommended by Dr. Meares—to wit: fumigation, flushing and cleansing—are, after all, only palliative, performing only a brief service; and when we consider the vast quantity of debris daily deposited into the sewers, the insignificance of the work of removing a few tons, consisting principally of sand, by manual labor, through the manholes, becomes apparent, for the small excavations so made are speedily filled up by the flowing mass.

Flushing will carry away the bulk of the accumulation, and should be practiced frequently, if only for æsthetic reasons; but this and all other cleaning methods will fail to keep the sewers free from putrescible matter. The conditions being favorable in a sewer, the process of fermentation commences quickly and continues actively

Producing Immense Quantities of Gas,

Which has the power, according to Prof. Doremas, of penetrating brick or stone walls, or any other porous material, and these bacteria possess an extraordinary power of multiplication. Thus, F. Cohn, a high authority on these matters, has calculated that "one single bacterium might, in less than five days, fill up, by its progeny, the whole ocean, supposing they found a sufficiency of food." There is never any scarcity of bacterial food in sewers. Reference is made to these things, not to discourage efforts at cleansing our sewers by fumigation and flushing, but to show the utter futility of such methods in securing any substantial or permanently beneficial results.

There should be no delay in repairing bursted and caved sewers, and their mouths should be kept open so that the corrupt sewage may have free and unobstructed egress to the bay. And of equal importance is thorough ventilation. Dr. Meares has stated the well-known fact, that sewer-gas is many times lighter than air, and ascends along and accumulates at the most elevated points ("Nob hill," for instance), where the pressure is the greatest, provided there are no vents at intermediate points. These facts being admitted, it is evident that, by placing

Ventilating Tubes at the Highest Points,

The dreaded gas could escape into cosmic space above the roofs of the houses, thus relieving the pressure in the sewers.

The accumulation (mainly sand) in the depressions, caused from settling or imperfect alignment of the sewers, might then be tolerated with comparative impunity, until the city shall be better able to bear the heavy expense of the new sewers proposed by Mr. Molineux, and I will venture to suggest that the Supervisors can render no greater service, after or aside from repairing, flushing and ventilating the sewers, as above proposed, the cost of which need not be great, than by following the example of the New York and Brooklyn authorities in relation to the house connections, which are notoriously bad in this city. Dr. Simpson tells us that three quarters of the dwelling-houses in the city are not protected by their

Plumbing Work

Against even gas. Now, in this lies the solution of the sewer-gas problem, and it is to be hoped that our authorities will move at once upon the works of the plumbers by adopting and enforcing the regulations of New York, printed copies of which can be obtained on application to the Board of Health of that progressive city, and by so doing they will give us the best possible protection against sewer-gas, and the expense would fall upon the house owners, where it properly belongs. This is a duty they owe to society, for public sanitation can only be made effective by applying to all a uniform rule of private hygiene. The law declares in unfaltering and equitable accents: "The people must make use of their own property in such a manner as not to injure that of others." The temptation exists to say more upon this subject, but I must forbear, and will submit some thoughts and facts which have led me to think that the exceptional weather this winter, which has no recorded parallel, has more to do with the high death rate than sewer gas. It is getting to be quite common, where communities are afflicted, as we have been this winter, to attribute every disease to sewer-gas, from corns on our

toes to "pinkeye of the horses," and people become crazed by the doleful predictions and queer and misleading remedial propositions of Supervisors, civil engineers and others.

Now, according to Dr. Simpson, the

Only Disease Prevailing Here.

As an epidemic, is measles, which is a disease common to all countries and it has no respect for persons, or places, breaking out in the palaces of the rich and the hovels of the poorest, and with no less frequency and virulence in the olean end isolated country residence, innocent of sewer gas, than in the crowded city. It is doubtless caused by some aerial infection, but with our present limited knowledge of the origin and nature of the microscopic denizens, and varying electrical conditions of the atmosphere, the wisest will hesitate to say that it is caused by sewer-gas. The air we breathe is rife with

Bacterial Life,

And so is, also, the water we drink; there is abundant testimony that the germs which produce the zymotic or "filth diseases," are quite as often introduced into our systems by water as by air, and since Spring Valley water is notoriously foul, it is quite as reasonable to ascribe the increased mortality to the impure water as to the sewer-gas, especially if we accept the declarations of Pasteur and Miquel, the highest authorities on these matters, that "the number of atmospheric bacterias is very small in winter and that they do not again increase until the ground becomes warm and dry, in the spring and summer." The announcement is even made by these scientists that "the vapor of water, arising from sewers, or from masses which are in a full state of putrifaction is always microgaphically pure, that a gas which comes from buried matters which are decomposing is always free from bacterias, or microbes, provided the air is in a certain state of *humidity*." If the theory, now generally accepted, that the atmospheric organisms, the miasmetic agents of fermentation, and the causes of zymotic diseases, are dormant and harmless during cold and damp weather, and which theory corresponds with our experience and observation in reference to yellow fever and kindred diseases, which are greatly mitigated and quickly disappear with the advent of frosty weather, is correct, it goes far to disprove the assertion that the present abnormal death-rate is due to sewer-gas, seeing that the atmosphere is cold and humid, and we should look in other directions for the cause of the trouble. There is good ground for suspecting the water, which is turbid with putrescible matter and more attention should be given to its

Purification by Means of Filtration.

It is known that contact with iron, as when stored in iron tanks, affects a speedy and perfect purification of water, the organisms being oxydized—burned—by contact with the iron and oxygen in the water, in which condition they are entirely harmless. Preference should, therefore, be given to the domestic filters in which the filtering-bed contains some preparation of oxide of iron. The small contrivances, in common use, which are attatched to the house-tape, are mere *strainers*, catching only the slimes and coarser contaminations, while the dangerous organisms and their germs, being microscopic, pass through each filters as freely as the water.

While I believe in the germ theory and am convinced that the cause of sickness and death is as often traceable to polluted water as to sewer gas, especially in this city, where the drinking water (Spring Valley) is turbid with impurities, and where the thermometrical and hygrometrical conditions of the atmosphere are unfavorable for active bacterial work, I think that the real cause of the present high death-rate is justly attributable to

The Exceptional Weather,

Which has no recorded parallel, and more particularly to the prevailing north wind. The electrical condition of this wind has not yet been ascertained, but we can all testify that it has a great thirst for moisture, to which quality we may safely ascribe its pernicious influence upon animal and vegetable life. Wind—air in motion—blowing from any direction, has great evaporative power, and the drier the wind the greater will be the evaporation. All know that evaporation is cold. The more rapid the evaporation the greater will be the cold produced. The effect of rapid evaporation of the moisture of the human skin is what we call a cold. The heat required to perform the *work* of evaporation is abstracted from the body, the pores of the skin close and cease to perform their functions as excretory organs, and the effete matters which should have been thrown off through these pores, clog the system, acting as a poison and producing inflammation and distress. It will settle upon the weakest part of the body, generally upon the respiratory organs. A slight cold may, and often does, under favoring circumstances, develop zymotic power that, like snake poison, ferments in the body till death is inevitable. The mortuary report for the last month—February—shows that fully one-half of the deaths resulted from diseases of the lungs and air passages, and half of these were children under ten years. Pneumonia is the prevalent complaint, and about 20% of the deaths in February are charged to that disease alone. It may be said that nearly all of these diseases of the lungs and air passages were caused by and commenced with a cold, and none of them are classed as zymotic, though some of the cases may have developed symptoms of that character. There were sixteen deaths from typhoid fever, which is certainly a "filth disease," but instead of being caused exclusively by sewer-gas, or aerial infection, the virus of this disease exists in, and is generally taken into our systems by the water we drink or the food we eat.

Three Parasitic Infectious Agencies

May and often do pass harmlessly through the body, but when they find a favorable nidus they multiply and produce a specific disease, such as cholera, or typhoid. Even diphtheria, which carried away 13 children last month, is not strictly a zymotic or "filth disease," but usually begins with a cold. Upon this point the report of Drs. Wood and Formad, recently published by the National Board of Health, is a very interesting paper. These medical gentleman conclude, after a long and thorough investigation, that "there is no difference between the micrococci of furred tongue, or ordinary sore throat and those of diptheria; the two are the same organism existing under different conditions. A common catarrh or simple inflammation of the mouth or throat, caused by a cold, in a weakly subject, as in a child, which has little resisting power may, under favorable conditions, end as adynamic diptheria with blood poisoning. The micrococcus which, directly or indirectly, causes the diptheria, is not a specific organism different from that common to healthy and inflamed throats, but is an active state of that organism which increases the inflammation and thus engendering an epidemic of diptheria, and there is clinically every reason to believe that the blood poison has been developed within the body of the patient." The special conditions favoring the changing of inactive into active micrococci remain yet to be studied, but that they are filth, or moisture, or temperature, or a combination of these, is questionable, for the simple reason that there are now, and have been from time immemorial, places that are over-crowded, filthy in every possible way—damp, hot and cold—in short every variety of combination of these and yet, where there is not and has not been any diptheria. This reasoning may safely be applied to many other diseases commonly called zymotic and supposed to be caused by sewer or other infectious gas or fluids, but which are really caused by cold, and I will venture to say that nine-tenths of the diseases that afflict mankind are due, primarily, to cold (excepting, of course, accidents and hereditary diseases), and my experience and observation have convinced me that they are preventable, in most cases. The prophylactic with which this may be accomplished is not new; it is simple, more agreeable and cheaper than medicine, and accessible to all. It consists in the conservation of the heat of the body by proper and sufficient clothing. Science, ancient and modern, teaches us the great truth, that energy of mind and strength of body are the effects of warmth, while depression of spirits and bodily weakness result from cold. Heat is vigor and life, and cold is disease and death. This is a wide subject and embraces other questions, but I shall confine myself to the important one, namely, "clothing."

We all know how easy it is

To Catch a Cold.

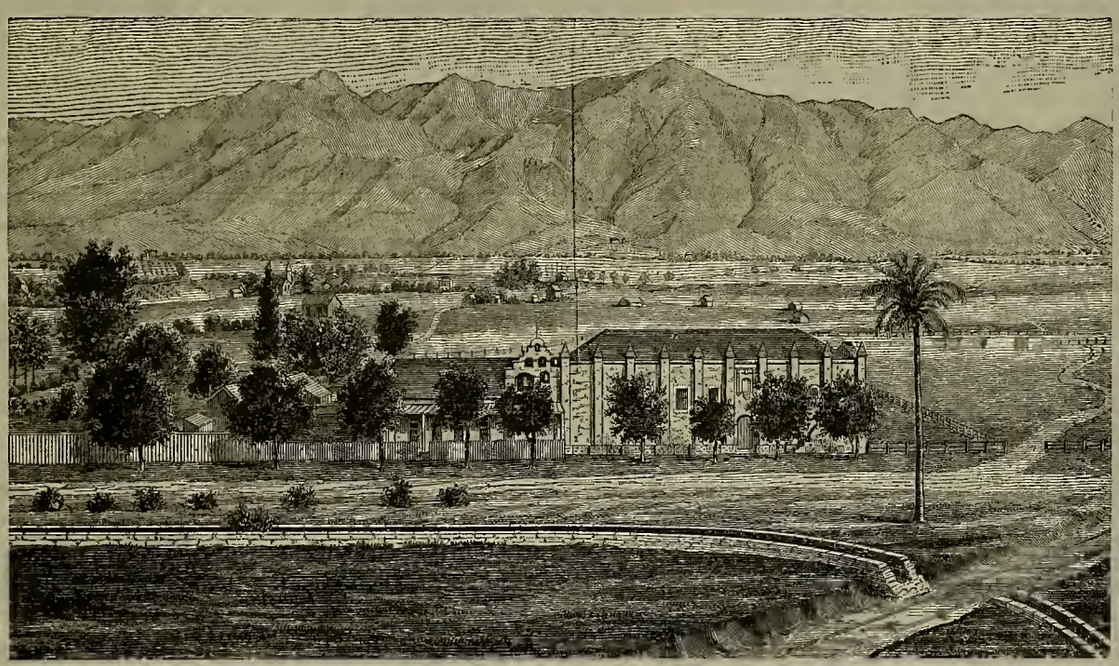
When the circulation is accelerated, and the blood thrown upon the surface, opening the pores of the skin and producing perspiration, we need only to expose ourselves to a draft to bring on a chill and sneezing, followed too often by most serious consequences. The chill is the result of the rapid evaporation of the moisture, by which process a great deal of heat is abstracted from the body. Weakly persons and children are most susceptible, and our north wind is particularly severe upon such persons when exposed to its refrigerative power under the conditions above named. The same agency, also, abstracts heat, though in less degree, by radiation, even when the body is in its normal condition. Comparative protection against these great evils may, however, be secured by insulating the body with good non-conducting clothing, which retains the heat and prevents *rapid* evaporation. If the over-heated body is allowed to cool off *slowly*, the danger is greatly mitigated, if not wholly averted. It is not the heaviest or thickest material which is the warmest. Wool is an excellent non-conductor, and is 300° better than cotton, and still better than linen. One thickness of wool is the equivalent of four thicknesses of cotton or linen in point of conductivity, and is also far more porous than the fibre plant. The latter absorbs the moisture and sticks to the body, leaving no air between and forming only one smooth evaporative surface, from which the moisture quickly evaporates, producing cold, whereas a wool or hair cover, being never entirely soaked, does not cling closely to the body, but forms a surface which is broken by air bubbles, permitting the moisture to percolate to and evaporate *slowly* on the outside, thus conserving the heat, while the skin remains in a blood rich state, and may perspire more freely than when exposed to a quick refrigeration, by evaporation and radiation from cotton or linen clothing. The

Importance of these Facts

Cannot be over-estimated, and people who wish further light and testimony, are urgently referred to the works of Dr. Pettenkofer, Prof. of Hygiene at the University of Munich, and Dr. Jaeger of Stuttgart, who have chosen, with highly satisfactory results, and earnestly recommend, for the conservation of the heat of the body, "only the material which nature has given for the same purpose to those mammals which are the most nearly related to man, namely, animal wool, even avoiding pocket and other linings of cotton."

In conclusion, I beg to say that I have tested the value of woolen clothing upon my own person and the members of my family with the most happy results. Several years ago our under-clothing consisted mainly of fiber plant; and we frequently contracted colds, resulting in obstinate chronic catarrhal and bronchial difficulties beyond the reach of approved pharmaceutical measures. We adopted the "normal clothing"—some members wearing double woolen-flannel under-garments—and since then have not only not taken any fresh colds, but the chronic difficulties referred to have disappeared, and this explains my enthusiasm over woolen clothing, and excites my sympathy for the little children who suffer most from improper and insufficient clothing, my observation being that a large majority wear no woolen clothing at all, and only a very few, especially girls, wear woollen under-clothing below the hips; below, the short, loose skirts are only a shield against the wind, while below the knee the only covering is a thin cotton stocking. In the light of these facts people, especially women, should strive to overcome the inertia of established habits and public opinion, and adopt the normal clothing of Pettenkofer and Jaeger, which will certainly increase the longevity of the community and enhance its comfort and enjoyment.

LAYMAN.



SAN GABRIEL MISSION, THE VALLEY AND THE SIERRA MADRE MOUNTAINS.

San Gabriel Mission.

We give a handsome engraving of San Gabriel Mission, one of the land-marks of the southern country. It is one of the best preserved of the old missions, and is well worth a visit from all who come into its vicinity:

Between San Diego, where the cross was first erected, and Monterey, their objective seat of empire, the fathers found no country so fertile and inviting as the San Gabriel valley. The forests were filled with game, wild foods of every kind were plentiful. The increase of live stock introduced by them was beyond all precedent. The olive and the vine flourished. Remains of the Vina Madre or Mother vineyard of San Gabriel may still be seen. With an eye to beauty as well as utility, these vineyards were intersected with walks shaded by fruit trees of every description, adorned with roses and flowering shrubs, and made pleasant by the sound of flowing waters brought from the surrounding hills. When the Mission Viego was abandoned for the more eligible site of which the church at San Gabriel is a monument, Father Salvadea reigned in supreme authority over some 15,000 souls. He believed in education by work, and his converts were no sooner baptised than they in turn were set to convert chaparral into pastures for the Lord's flocks; he built the mill and dam at the Kewen place, enclosed many miles of the domain with hedges of tuna, laid out a beautiful square around the church with a sun-dial in the center, planted the first orange orchard, and brought the date palm, it is said, from the city of Mexico, to whisper at vesper time of the triumphs of the redeemed. How dream-like and unreal all this seems as the train goes whirling past the lonely palm tree and the old sanctuary, and is lost in the distance.

The old ground of the *padres* it now the site of some of the most famous orchards and vineyards of the State.

Death of Owen O'Neil.

We announce with deep grief the sudden death of Owen O'Neil, who was for several years proof-reader for Dewey & Co's publications, and for two years has edited the *Pacific States Watchman*. Mr. O'Neil's death was strangely sudden. He was in his usual good health on Monday morning. After taking a warm salt-water bath at North Beach, he went under the cold shower and was suddenly struck down. He retained consciousness only long enough to tell his residence, where he was immediately conveyed. He remained unconscious for several hours and then died quietly. Deceased was well known among the fraternal societies, and was a member of Olympic Lodge, A. O. U. W., and Bohemian Council of the American Legion of Honor. Among his fellow workers Mr. O'Neil was universally liked and respected as an energetic, even-tempered and industrious young man. He was most earnestly devoted to his work, and had a bright future as an honest and conscientious journalistic worker. His loss will be deeply felt in this office.

Mr. O'Neil's funeral was held under the auspices of the societies of which he was a member, on Wednesday afternoon, and was attended by the employes of Dewey & Co. Floral offerings were numerous and beautiful. Mr. O'Neil leaves a wife and two bright little boys which were the delight of their father's heart. His memory will be long cherished.

A SPECIAL from Benson says: The New Mexico and Arizona Railroad was opened for freight and passengers this morning. The fare from Benson to Contention was $1 50; general merchandise, 11 cents per 100 pounds. The trains connect with all Southern Pacific trains at Contention, and stages connect for Tombstone, which is nine miles from Contention.

CHICAGO **FRASER & CHALMERS,** ILLINOIS.

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterne,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, improved form. Bullion and Copper Moulds and Ladles, Litbarge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. B. Haggin for Giant and Old Abe Cn, Black Hills also Corliss Pumping Engines, 26x60, for Hoisting and Pumping Works, for 2,000 feet deep. **Baby Hoists for Prospecting, 4 H. P. to 6 H. P.**

Wire Rope, Safety Cages and any Size and Forms of Cars. McCaskell's Patent Car Wheels and Axles—Best in Use.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois. New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

Frue Ore Concentrator, or Vanner Mills.

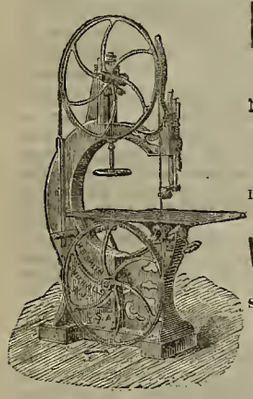
Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail.

HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,750 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. BOILERS of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.



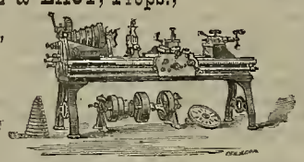
Berry & Place Machine Co.,

PARKE & LACY, Props.,

No. 323 & 325 Market St.,

San Francisco,

CAL.



Importers and Dealers in every Variety of

Wood and Iron Working Machinery,

STEAM PUMPS,

Stationary, Portable and Hoisting Engines and Boilers Sawmills, Shingle Mills, Emery Wheels and Grinders. Gardner Governors, Planer Knives, Sand Paper in Rolls, together with a general line of Mining and Mill Supplies, including Leather Belting, Rubber Belting Packing and Hose.

"FRUE" ORE CONCENTRATORS.

I have on hand and for sale, at LOW PRICES, a number of the above Concentrators, of the latest pattern and in perfect order.

JOSHUA HENDY,

Manufacturer of Quartz and Saw Mill Machinery

AGENT FOR "BAKER'S" ROTARY PRESSURE BLOWERS,

Hot Polished Shafting from the Akron Iron Company, Ohio. Also, "P. Blaisdell & Co.'s" Machinists' Tools. A Large Stock of New and Second hand Machinery at Machine Works.

Nos. 49 and 51 Fremont Street, San Francisco.

$1,000 CHALLENGE!

THE FRUE ORE CONCENTRATOR.

Nearly 300 are now in use, giving entire satisfaction. Awarded First Premium and Silver Medal at the Industrial Fair for 1880 of the Mechanics' Institute of San Francisco, Cal.

Saves from 50 to 100 per cent. more than any other Concentrator in use, and concentrations are clean from the first working. The wear and tear are merely nominal; water required is less than in any other wet Concentrator; the power required per machine is less than one-half horse power; the labor required is light, one man on a watch can attend to sixteen machines.

We challenge any other Concentrator in use for a fair and impartial competitive trial, side by side, for stakes of $1,000 each, and we mean business.

☞ A machine with all improvements can be seen in working order and ready to make tests, at the office of Hinckley, Spiers & Hayes, 220 Fremont street.

ADAMS & CARTER, Agents, Room 7 No. 109 California Street, S. F.

LUTHER WAGONER. JOHN HAYS HAMMOND.

WAGONER & HAMMOND,

Mining Engineers,

Special attention paid to Examinations of Mines, plans and reports furnished.

C. A. LUCKHARDT & CO,
(Formerly Huhn & Luckhardt.)
Mining Engineers and Metallurgists

JOHN TAYLOR & CO.,
IMPORTERS OF AND DEALERS IN
Assayers' Materials,
MINE and MILL SUPPLIES,
CHEMICAL APPARATUS AND CHEMICALS, DRUGGISTS' GLASSWARE AND SUNDRIES, Etc.
118 and 120 Market Street, and 15 and 17 California St., San Francisco.

We would call the attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our full stock of Balances, Furnaces, Muffles, Crucibles, Scorifiers, etc., including, also, a full stock of Chemicals.
Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast, we feel confident from our experience we can well suit the demand for these goods both as to quality and price. Our *New Illustrated Catalogue*, with prices, will be sent on application.
☞Our Gold and Silver Tables, showing the value per ounce Troy at different degrees of fineness, and valuable tables for computation of assays in grains and grammes, will be sent free upon application. Agents for the Patent Plumbago Crucible Co., London, England.

JOHN TAYLOR & CO.

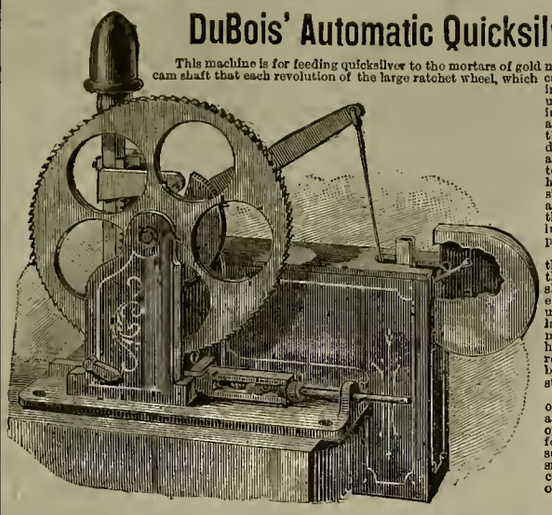
SHEET IRON PIPE.

FRANCIS SMITH & CO.,
Manufacturers of
THE PATENT CHANNEL IRON WHEELBARROWS.
THE STRONGEST BARROW MADE. These Barrows are made by Superior Workmen, and of the best material. All sizes kept constantly on hand

SHEET IRON PIPE.
Lap-Welded Pipe, all Sizes, from Three to Six Inches. Arteslan Well Pipe. Also, Galvanized Iron Boilers, from 25 to 100 Gallons.
Iron Cut, Punched, and Formed for making Pipe on ground, where required. All kinds of Tools supplied for making Pipes. Estimates given when required. Are prepared for coating all size of Pipes with a composition of Coal Tar and Asphaltum.
Office and Manufactory, 130 Beale Street, San Francisco.

SHEET IRON PIPE.

DuBois' Automatic Quicksilver Feeder.



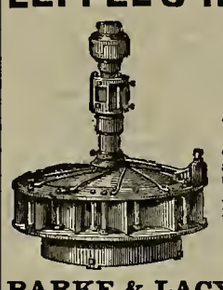
This machine is for feeding quicksilver to the mortars of gold mills. It is so connected to the cam shaft that each revolution of the large ratchet wheel, which can be regulated to revolve once in one, two, three or four minutes, as desired, dips a small cup into a reservoir of quicksilver, and by a trip of the cam, empties the contents into a pipe leading down to the mortar, supplying an exact quantity at regular intervals, superseding the ordinary hand feeding, which is of necessity subject to great irregularity, and liable to neglect. It renders the amalgamation of all the gold in the pulp equally certain and perfect.
The mechanism to produce this depression and elevation of the cup, is driven by the cam shaft, similarly to the self-feeders, over which so much ingenuity has been expended to regulate the delivery of ore to the mortar. As it is to be desired to have the ore go in constantly and regularly, so it is equally desirable to have the mercury fed constantly and regularly.
A chief point of excellence of this machine is, that it allows the quantity of mercury which would be otherwise fed in mass, in one hour, to be subdivided into a number of small portions, and fed almost continuously; *i. e.*, from every one to four minutes.
Price, complete, $100.

For Sale by **WHITNEY & MARSHALL,** Sole Agents
22 & 24 Fremont St., San Francisco.
Dealers in Iron, Steel, Hardware and Mining Supplies, Wrought Iron Pipe and Fittings, Pump Columns, Wire Rope, etc. A large stock of Boiler, Plate and Sheet Iron of every description.

MOREY & SPERRY,
MANUFACTURERS OF
Gold and Silver Grinding and Amalgamating Machinery

HOWLAND'S PULVERIZER Takes the Place of the Cumbersome Stamp Mill and can be put up in one day ready for work.
IT HAS BEEN FULLY PROVED AND TESTED.
It weighs complete, 7,000 pounds. It costs $1,500 ready for the belt. Will crush one ton per hour of hard quartz that will pass through a 40-mesh screen. The wear is less than in the stamp mill. Its wearing parts are plain castings and can be dropped into position in a few moments, as shown by the letters A, B and C, no bolts or keys are required; it can be set upon the floor of a mill with no expense for foundations, and can be used to crush and work in charges or continuous. It will amalgamate either gold or silver ores, making a simple, cheap and effective mill, it requires twelve-horse power.
Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver ores Chloridizing Furnaces, Retorts, Rock Drills Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill supplies Iron Work complete for Wood Frames, also
SPERRY'S WROUGHT IRON FRAME FOR STAMP MILLS.
☞Great saving in time and money over the Wood Frame. It is made complete with Wrought Iron Frame ready to put upon the foundation. We construct Mills with Stamps weighing from 350 to 900 pounds for Gold and Silver Ores. Wet or Dry Crushing Mortars.
MOREY & SPERRY—Warerooms, 92 and 94 Liberty St., N. Y.

LEFFEL'S IMPROVED WATER WHEEL.



PRICES REDUCED!
PATENTS REISSUED 1868.
The "OLD RELIABLE" with improvements, making it
THE MOST PERFECT TURBINE NOW IN USE.
Comprising the **Largest** and the **Smallest** Wheels, under both the **Highest** and **Lowest** head used in this country. Our new Illustrated Book sent free to those owning water power.
Those improving water power should not fail to write us for **New Prices**, before buying elsewhere. New Shops and New Machinery are provided for making this Wheel. Address
JAMES LEFFEL & CO., Springfield, Ohio, and 110 Liberty St., N. Y. City.
PARKE & LACY, Sole Agents, 21 and 23 Fremont St., S. F.

STEEL CASTINGS
FROM 1-4 TO 10,000 lbs. WEIGHT.
True to pattern, sound and solid, of unequaled strength, toughness and durability.
An invaluable substitute for forgings or cast-iron requiring three-fold strength.
Gearing of all kinds, Shoes, Dies, Hammerheads, Crossheads for Locomotives, etc.
15,000 Crank Shafts and 10,000 Gear Wheels of this Steel now running prove its superiority over other Steel Castings.
CRANK SHAFTS, SHOES, DIES and GEARING specialties.
Circulars and Price Lists free. Address

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

From the official list of U. S. Patents in DEWEY & Co.'s SCIENTIFIC PRESS PATENT AGENCY, No. 252 Market St., S. F.

FOR THE WEEK ENDING MARCH 21, 1882.

255,135—DESOLPHORIZING FURNACE—A Blatchly, S. F.
255,259—WATER WHEEL—Daniel Donnelly, Sutter Creek, Cal.
256,299—CANE, UMBRELLA HANDLE, ETC.—Thos. V. Keam, Keam's Canyon, A. T.
255,301—SHOE—David Lubin, Sacramento, Cal.
255,191—CLEARING SLOTS OF WIRE ROPS, R. R.—John Powers, S. F.
255,335—HOSE COUPLING—E. A. Rix, S. F.
255,372—CONDENSER FOR STEAM ENGINES—R. E. Williams, Grass Valley, Cal.
256,334—SIDE SADDLE—L. A. Reister, Chico, Cal.

FOR THE WEEK ENDING MARCH 28, 1882.

255,481—GATE—Charles H. Allison, Elmira, Cal.
255,584—FIRE ESCAPE LADDER—R. F. Bridewell, S. F.
255,601—CAR-COUPLING—L. J. Cralle, Santa Rosa, Cal.
255,602—FAUIT DRIER—Charles A. Curran, Albany, Oregon.
255,509—STEAM GENERATOR—Wm. D. Horker, Oakland, Cal.
256,642—BOTTLE AND BOTTLE ATTACHMENT—D. Lubin, Sacramento.
255,533—PICK—Eben R. Ray, Bodie, Cal.
255,623—PIPE-COUPLING—S. Lighthurne, Jr., S. F.
255,678—PULVERIZING MILL—Wm. C. Salmon, Portland, Oregon.
255,736—VEHICLE BOLSTER—Dyas Shelton, Santa Rosa, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast Inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

FARM GATE.—Charles H. Allison, Elmira, Solano county, Cal. No. 255,481. Dated March 28th, 1882. This is a gate made longer than the width of the gate, opening and having one of its hare supported upon rollere or pulleys, so that the gate may he moved backward and forward aoross the gate, opening and halanced upon the rollers. In combination with this sliding-gate is a wheel, mounted npon the posts of the gate, opening and having ropes or cords wound upon it from opposite sides and leading down heneath pnlleys, and thence to the ende of ths gate, so that when the wheel is turned by one of the cranke which project to each side, the ropes will operate to move the gate upon its rollers, and thus open or close it.. In some cases the ropss may pass directly from the wheel to the tops of the gate-posts, which may extend upward.

PIPE COUPLING.—Stafford Ligbthurne, Jr., assignor of one-half to J. R. Mackenzie, S. F. No. 255,523. Dated March 28th. This improvement in pipe coupling consists in a novel formation of locking-lugs and slots on the meeting ends of the coupling hy which the two parts may he firmly united, and in combination with these, the inventor employs a peculiarly constructed elastic ring, hy which he is enahled to make a perfectly tight joint. The present invention is an improvement on a coupling patented hy the eame inventor in 1877. A cap is employed to protect the end of any coupling when separated, and an implement hy which the locking device may he unclasped or released is also used.

MINING PICK.—E. R. Ray, Bodie. No. 255,533. Dated March 28, 1882. This invention is in that class of picks in which the points are adapted to he easily fitted to and removed from the stock. It coneiets in a novel construction of the stock and points, with corresponding shoulders, and sockets wherehy the latter may he readily and securely fitted to the former.

Business Offices and Sunny Rooms to Let.

We have some desirable rooms to let adjoining the offices of this paper which will he rented on favorable terms. Stair entrance, No. 252 Market St. Elevator, No. 12 Front St. Parties wishing offices, etc., will do well to call and see them. DEWEY & CO.

Sewing Machines.

Several first-class styles, good as new, will be sold at a bargain. Call on or address H. F. D., at this office.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

PERSONS receiving a sample copy of the MINING AND SCIENTIFIC PRESS *with this notice marked*, are requested to examine the merits of the same, and consider fairly its claims for support, and if consistent, subscribe for the paper through the P. M. or agent delivering it, or otherwise. We shall send it, on trial, at the rate of $4 per annum for any period the reader may wish. Please notice our terms elsewhere, and if desired, send for further samples and information. Those who can circulate this No. further to our advantage are invited to do so.

Production of the Precious Metals.—No. 3.

An Abstract of the Ceneué Monograph on the Bullion Output of the Country.

Placer mines, with the exception of pocket mines. and branch mines, require no reduciog process; and in the two exceptions named the mill process is not always a necessary concomitant; in the former, in fact, hnt rarely. Various systems of reduction hy chlorination and amalgamation have also heen applied to black sand deposits and refractory conglomerates containing placer gold, hut not to an extent affecting the general principle of classification here maintained.*

Statistics of the Pacific Divieion.

CALIFORNIA.

In production of gold California still bolds the first place. The amount of silver contributed hy California is relatively small, and comes mainly from two adjoining counties, Inyo and Mono. 57 amalgamating mills, concentration and leaching works, 9 arastras, and four smelting works in this State. These include most of the more important establishments, and are supplemented hy general reports covering, in some cases, whole districts. But, with all the care taken hy tbe census experts to thoronghly cover the ground, the snbject was hy no means exhausted, and in several cases in the accompanying tahulation resort has heen had to information from outside sonrces.

California furnishes 71.47% of the total placer product of the United States, and 40.09% of the total gold product of the deep mines, or 51.38% of the total gold product of the country (from all sourcss). The yield in silver, however, is only 2.80% of the total, California standing sixth in rank as a producer of the latter metal. In proportion to its area, again, California leads in production of gold, with an average of $108.30 per square mile; is sixth in its silver yield of $6.84 per sqnare mile; and third as to its output of hoth metals, $115.14 per square mile. As the population of the State hae largely increased, while the mine production has remained nearly at a standstill for some years, the showing in relation to popnlation is less favorahle, the yield of gold heing only $19.84, silver, $1.25, and that of hoth the precions metals only $21.09 per capita, placing California fifth as to gold, and eighth as to silver and the total, in the rank of the United States. The prosperity of the Stats is not, however, dependent npon its mines in the same degree as formerly, agriculture and mannfacturing having outstripped the earlier industry.

There are a larger numher of actively working mines in California than in any other State or Territory, as, owing to the settled condition, transportation facilities, and comparative cheapnese of labor and supplies, it is possihle to mine deposits of lower-grade than could he made profitahle in localitiee having loss advantagee of position. The resnlt is that there are, hesides a few large incorporated companies, a great many mining properties worked on the small scale, hut still profitably, hy individual owners. The collection of accurate statistics regarding these smaller claims is a very tedious and also somewhat uncertain matter. Schedule returns were received from 128 deep mines, 147 placer mines,

*Estimated.

*In each of the tables of production and throughout this discussion the following explanations apply: The short ton of 2,000 pounds is invariably used. The ore tonnage is stated in gross tons; the assay values are of net tons, without allowance for moisture. Mint values are assumed in all cases. The weight of bullion is given in troy ounces of fine metal. The gold ounce is taken at $20.671834 and the silver ounce at $1.2929. A statement of the estimated market value of the silver is elsewhere appended. No account is taken of the value of the silver alloyed with placer gold in the primary production tables, as, with very few exceptions, no allowance is made for it in selling. This is treated of separately and the proper addition made in the final summary. The bullion yield is given according to the county in which the ore producing it was raised, without regard to the locality where the ore was reduced. This method of stating the product apportions it with reference to the original source, so far as it is practicable to trace it. Were the yield to be credited to the reduction works, Omaha, Chicago, St. Louis, Newark, New York and other points remote from the mines, would appear as large producing centers.

Individual estimated amounts are designated by an asterisk (*), and where such estimates form a considerable proportion of the totals the fact is similarly indicated.

*Estimated.

THE State Mining Bureau, No. 212 Sutter street, is open to the public from 10 o'clock A. M., to 5 o'clock P. M. daily, (Sundays excepted). Henry G. Hanks, State Mineralogist.

A TURNED LEAF will point ont the article supposed to be of special interest to persons receiving sample copies of this paper.

ANNUAL STATISTICIAN of 1882.—"It is the most complete and accurate work of its kind in the world."—*S. F. Call.* Address L. P. McCarty, 502 Taylor st. Price, $4.

Mining and Other Companies.

Persone intereeted in incorporations will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for advertising.

Bullion Mining Company.—Location of Principal place of business, San Francisco, California. Location of works, Gold Hill Mining District, Storey county, Nevada.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 29th day of March, 1882, an assessment (No. 23) of Thirty (30c) cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, Room 3, Safe Deposit Building, 328 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the second (2d) day of May, 1882, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Wednesday, the twenty-fourth (24th) day of May, 1882, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

J. M. BRAZELL, Secretary.

Office—Room 3, Safe Deposit Building, No. 328 Montgomery street, San Francisco, Cal.

DIVIDEND NOTICE.

OFFICE OF THE

Standard Consolidated Mining Company.

San Francisco, April 1, 1882.

At a meeting of the Board of Directors of the above named Company, held this day, dividend No. 40, of seventy-five cents (75c) per share was declared, payable on Wednesday, April 13, 1882, at the office in this city, or at the Farmers' Loan and Trust Company, in New York. WM. WILLIS, Secretary.

Office—Room No. 29 Nevada Block, No. 309 Montgomery Street, San Francisco, Cal.

MINERS' HORSE-WHIM.

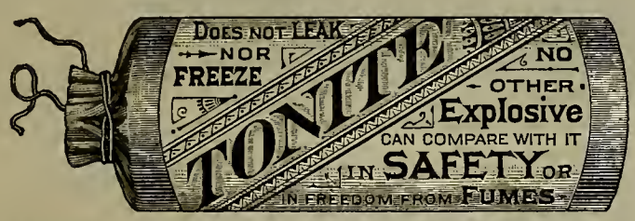
One Horse can easily heist over 1,000 pounds at a depth of 500 feet. The whim is mainly built of wrought iron. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The standard of the whim is bolted to bed-timbers, thus avoiding all frame work. When required these whims are made in sections to pack on mules.

From Black Hills "Pioneer," March 21, 1882.

The miner who was so horribly mutilated by an explosion of a stick of Giant Powder at the Grand Junction was not chopping the stick, as reported. He was rolling it between his hands to warm and soften it. This terrible accident should teach those who handle this explosive that too much care cannot be observed, There are very many foolish ideas concerning Giant Powder that are liable to lead to accidents.

From Black Hills "Pioneer," March 28, 1882.

On Saturday, James Seeley had several sticks of Giant Powder in his boot legs and went into the blacksmith shop, when a spark of fire from the forge set his pants on fire, the powder also catching and burning his leg quite seriously. When the other boys discovered the fire there was a scattering from that shop too lively to talk about.



BY USING TONITE

Accidents like the above, and many of a similar nature occurring with Compounds of Nitro-Glycerine, may be **Entirely Avoided.**

JOINT FOR SHEET METAL PIPE.

RE-ISSUE PATENT NO. 8,214 TO JOSEPH MOORE AND FRANCIS SMITH.

"The invention consists in connecting the meeting ends of the pipes firmly together and placing a band or tube around the outside of the meeting ends, which is larger in diameter than the pipes, and which is long enough to extend a distance on each side of the joint and then filling the space between the outside band or tube and the pipe, with a packing of lead or other soft material, either by casting or tamping."—(Extract from specification of Patent).

These joints have been tested for 3 years, and are undoubtedly the best joint made for sheet-iron pipes—THE BEST AND CHEAPEST.

ANY INFRINGEMENT WILL BE PROSECUTED.

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

DEWEY & CO.'S Scientific Press Patent Agency.

[ESTABLISHED 1860.]

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 252 Market St., S. F.

VIGORIT POWDER.

NO ACCIDENT HAS EVER HAPPENED.

ALL POWDERS manufactured by the California Vigorit Powder Co. are SUBMITTED during the course of manufacture TO SCIENTIFIC and accurate TESTS for safety and strength.

They are tested for Safety against Friction, Fire, a Temperature of 212° Fahr., and the various shocks to which Powder is liable in practical handling.

The following qualities are common to all grades of Powder manufactured by the Company:

Safety, Non-Leakage; Freedom from Noxious Gases; Uniformity and Strength.

If consumers desire it, the EXACT STRENGTH of any Powder shipped to them will be GIVEN IN FOOT POUNDS.
☞Send for Pamphlet showing methods of testing the different qualities of all Powders.
The Company manufactures:

DETONITE.

This is an explosive involving new principles and recently patented. It is the **Strongest Powder ever placed on the Market,** in this country or abroad. It is the **Safest Strong Powder ever made.** For very refractory rock this Powder is the most economical in the market.

VIGORIT, No. 1, XX.

This Powder is **Stronger than the Highest Grades of Hercules or Giant.** It is only surpassed by "Detonite." It is suitable for hard rock.

VIGORIT, No. 1.

For general work this Powder has no superior. It has the advantage over Giant, Hercules or Vulcan in safety and freedom from noxious fumes.

VIGORIT, No. 2.

Equal to any corresponding Grade in the Market.

LOW POWDER.

VIGORIT, L. P.

This is a Powder suitable for **Bank Blasting, Log Splitting** or the work generally in which Black Powder can be used. It is STRONGER THAN BLACK POWDER, having from twice to ten times the effective strength, depending on resistance. It is **Superior to Judson Powder,** in being more sensitive to the cap and more convenient in handling.

Best Qualities of FUSE and CAPS sold at Lowest Rates.

CALIFORNIA VIGORIT POWDER CO., **ENGLISH & WRIGHT, Agents**
No 327 Pine St., San Francisco.

VULCAN BLASTING POWDER.

—THE MOST ECONOMICAL AND BEST—

Nitro-Glycerine Explosive in the Market.

In the suit of the Giant Powder Co. against the Vulcan Powder Co. for *alleged* infringement of Patent, it was held that the Giant Powder Patent was INVALID.

Nos. 1, 2 and 3 Vulcan,

Each grade superior to like numbers of any other Nitro-Glycerine Powder in the market.

VULCAN B. B.,

Superior to Black, Judson or any low grade Powder for Bank Blasts, Railroad work, or any work where Black Powder has been heretofore employed.

TRIPLE FORCE CAPS AND ALL GRADES OF FUSE.

The CONSUMER'S COMPANY sell the best Powder at the lowest rates.

Office—218 California St., San Francisco.

GIANT POWDER

MANUFACTURED UNDER A. NOBEL'S ORIGINAL AND ONLY VALID NITRO-GLYCERINE PATENTS.

Nos. ONE, TWO and THREE.

Stronger, Better and Safer than any other High Explosive

Judson Powder

IS NOW USED IN ALL LARGE HYDRAULIC CLAIMS.

It breaks more ground, pulverizes it better, saves time and money, and is superseding the ordinary powder wherever it is tried. ☞Triple Force Caps and all Grades of Fuse.

SAN FRANCISCO, SATURDAY, APRIL 15, 1882.

VOLUME XLIV Number 15.

Barrel Amalgamation.

In working silver ores on this coast hy harrel amalgamation, the following process has heen carried ont: The barrels are charged with abont 2,000 lbs. of ore, mixed with water enongh to make a moderately thick paste. Before adding quicksilver, the charge is revolved for two or three honrs in the harrel with several hnndred ponnds of scrap iron. The object of this is to effect a partial reduction of the chlorides present, which wonld otherwise be performed at the expense of the qnicksilver. The chloride of silver is partly rednced hy the metallio iron, and is subsequently amalgamated hy the qnicksilver. The same is true of the lead and copper. Qnicksilver is added according to the richness of the ore, nsnally varying from 250 to 500 or more pounds.

The harrel is rnn two honrs at 12 or 15 revolutions a minnte, and then examined, that the consistency of the paste may he ascertained. If the latter is too thin, the qnicksilver settles on the hottom. This condition is remedied hy the addition of more roasted ore, while, if too thick for the most favorahle disposition of the qnicksilver, more water is added. The harrel is then allowed to revolve again for 14 honrs, making 15 revolntions per minnte. The whole time occnpied from the charging to the discharging of the harrel is 18 or 20 honrs.

When the amalgamation is complete, the paste is thinned hy the addition of water, and the qnicksilver and amalgam are thns allowed to collect on the bottom of the harrel. Below the harrels is a large hopper, or funnel-shaped contrivance, sloping down from the fonr sides to a common center. When a harrel is to he discharged, a small plng in the side is loosened while tnrned npward, and when the harrel is revolved so that the plng is downward, it is drawn ont hy hand. The qnicksilver and amalgam are discharged into the hopper or funnel, and are allowed to run from the harrel nntil the pnlp hegins to follow, when the plng is replaced.

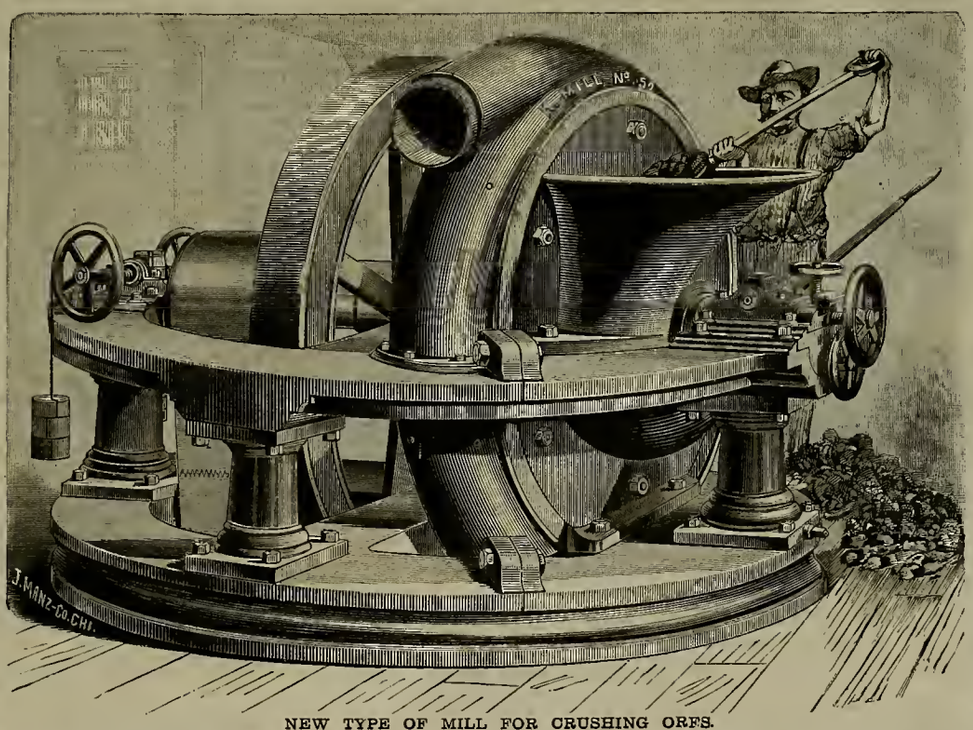
When all the harrels ready for that pnrpose are discharged, the amalgam in the hopper is carefnlly collected and washed, and afterward cleaned in a common pan like those in nse in other mills for similar pnrposes. The etraining of quicksilver and retorting of amalgam is performed in the nsnal manner. After the hopper below the harrels has heen cleaned of all the qnicksilver discharged into it, the residue is permitted to flow from the harrels and to run down into a large agitator, 8 or 10 ft. deep and 12 or 15 ft. in diameter, in which stirring arms are revolving. By this means the nnseparated qnicksilver and amalgam are allowed to settle, and the concentrations of this vessel are worked over in pans in the common way, while the mass of tailings, passing from the settler, are subjected to further methods of concentration and subseqnent treatment.

THE immigration hy ocean steamers to Oregon is now ahont 4,000 per month. Of these ahont 80% are sctnal settlers, who hring with them from $500 to $1,000 each, and nsually their honsehold effects. Ahout one-third go to the Umpqua and Rogue River valleys, in southern Oregon, the remainder heing equally divided hetween Walla Walla valley, the Palouse rogion, Yakima connty, Umatilla county, Oregon, and the plain hetween the Northern Pacific railroad and Columhia river.

IT oosts thie country eight hnndred times as muoh for intoxicants as it doee to pay salaries of the olergy. The figures are $2,200,000,000 and $60,000,000.

A New Ore Mill.

We present two engravings of a new and powerfnl grinding mill, made hy the Northwestern Fertilizing Co., Chicago, Ill., for the purpose of grinding all hard snhstanoes, such as rock, iron or gold ore, cements, eto. The advantages olaimed for the mill are simplicity of constrnction, economy in grinding, a large capacity for work and the complete adaptation of the mill to any class ot grinding reqnired. It is adjusted to any grade, fine or ooarse, hy means of a simple set screw. By a mechanical device in the construction of the mill, when large pieces of iron enter, the grinding faces open five inches, and the iron is thrown ont withont snstaining any injnry whatever. Its capacity for grinding



NEW TYPE OF MILL FOR CRUSHING ORES.

rock to a 60-mesh screen is one ton per honr—20 tons in 20 hours.

The grinding faces are made of metal that resists the wear; hnt the great advantage is in the constrnction of the mill in making the rock pulverize itself, rather than hy ruhhing against the grinding faces. The cost of repairs is reduced to a minimum, the grinding faces having run, we are told, three months on rock withnut renewal.

It requires ahout 25-horse power to run the mill to its fnll capacity. No foundation is reqnired or holts needed to hold the mill in place. Its weight, 23,000 lbs., holds it in position. When in motion it is noiseless. The ores must he dry when ground. This mill is its own crusher, and no preparation of the rock is required. The illustration on this page shows the mill closed ready for work. The engraving, on page 249, shows the mill open with grinding faces exposed. The mannfactnrers have heen running this mill on rock for the past 18 months and, from their experience, they helieve the mill stande without a rival, for capacity and economy in redncing gold, iron, or other ores to powder. They inform ue that they are now grinding iron ore through 60-mesh screen, at the rate of one ton per hour.

A MINE called the "Little Devil" hrought $6,000 in a sale at Tombstone the other day.

Phosphorescent Rock.

At the meeting of the San Francisco Microscopical Society this week, Mr. H. G. Hanks, State Mineralogist, read the following paper:

Some time since, D. B. Hnntley, of the Geological Corps of the Tenth Census of the United States, hrought to the State Mining Bureau a mineral, with the statement that it had shown certain peculiarities which led the miners to call it hy the rather startling name of "Hellfire rock."

The property known to mineralogists as phosphorescence is not confined to one mineral species, nor is it very nncommon. Bnt in this specimen it is so strongly marked that there is some excuse for the refusal on the part of some of the miners to work in the mine. When striking their picks into this formation, flashes of light were seen, which they regarded with enperstitious alarm.

The locality in detail is, Shenandoah mine, Snake Creek district, Wasatch oounty, Utah.

A chemical examination shows this mineral to he an impnre dolomite. It is interesting, not only from its remarkahle phosphorescence when rnhhed with any hsrd substance in the dark, hnt from its heautifnl crystalline appearance under the microscope, and the ease with which it can he rednced to a crystalline powder, even hy crnshing hetween the fingers.

In Cleveland's Mineralogy we find it stated that eome varieties of dolomite are phosphorescent in the dark, either hy friction or when thrown on a shovel which has heen allowed to cool just helow the point of redness.

The lights heing turned down, Mr. Hanks produced the phosphorescence heantifully hy scratching the specimen with a knife-hlade. It was of a hright reddish-yellow or orange color, and it was olearly seen how a miner conld he agitated hy striking snch infernal material in his ouhterranean walks.

LEAD hars are now ehipped regnlarly from Palisade to New Orleans hy way of the Sonthern Pacific railroad. Satnrday ten cars of this metal were here at one time. It looked strange to old settlers to see freight hilled on the Humboldt sent west to New Orleans hy rail.—*Winnemucca Silver State*

[illegible] Ores.

What becom[illegible] thousand dollars a ton" mines that [illegible] every year? At what mills are the ores [illegible] try these high percentages of [illegible] a day passes, that we do not see in some journal that the lucky prospectors, so and so, have found a claim, the ore of which is very rich, assays way up in the hundreds or the thousands.

The strange thing is, we never hear of the mines again. When a mill begins to experiment on the rock, it tells a different story from what the assayers' scales did. If $500 rock proves $50, it pays first rate as a general thing, but the percentage even is seldom maintained.

The truth of the matter is, it is not the "rich" mines, hnt those with plenty of ore that pay. If the ore will pay a fair profit, over and above expenses, the mine is apt to he very mnch more profitable than when a few tons figure np high in the thousands. Mines with many tons of rich ore are all phenomenal. They occur so seldom that they are scarcely worth taking into account in prospecting. Of course, we naturally, when hnnting for a prize, want the higgest one there is to he had; hnt we ought not pass hy a small one in looking for a large one.

These olaims, with ore which assay way up in the thousande, very seldom prodnce mnch of it. After one discounts the selected specimen, for what an average would be, and discount the assay valne from the real value, and the real value from what it will mill, we find we have hronght it down considerahly.

It is not hest, therefore, for men to he too sangnine when they hear of high assaying rock. It is true, a long array of figures on an assayer's certificate has a charm for many, and produces an excitement it is difficult to overcome. But even the most self-deceiving prospector will acknowledge to himself that the figures are safer on the paper than if hronght to the test. He will trot around and try to sell a mine for a price that a dozen or two tons of the presnmed rich ore wonld yield. If miners will hut consider the snhject, they will remember that the most famous mines which have paid their millions, are those which have yielded ahundantly of an average ore; and that these mines last longest also. The thousand dollar a ton claim, does not last very long.

DEATH OF REV. L. HAMILTON.—The friends of Rev. Lanrentine Hamilton, in all parts of the State, will he pained to learn of his sudden demise last Snnday morning. While reading his sermon he was stricken with serous apoplexy in his pulpit, and died without recovering conscionsness. Rev. Mr. Hamilton was greatly loved hy his people, and his death causes profound grief. Memorial services were held last Snnday in the Iodependent church, Oakland, and further services, significant of the hereavement of the chnrch, will he held next Sunday afternoon.

THE Bonanza Gravel claim at Howland Flat, says the *Mountain Messenger*, averaged in their last clean np $150 to the carload. We hear there is now a fair proepect of soon discovering the lost pay-channel, and sincerely trust that such may he the case, eo that our venturesome English oousine over the waters may ohtain a handsome interest on the large sum they have risked in developing our gravel depoeits.

A FURNACE is to he erected at Soda springs, Nev., to reduce copper ore.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Northern California Mines.

A Rich, but Neglected Region.

Editors Press:—I have been a subscriber and reader of the Press for many years and have often noticed the limited amount of mining news from this, the northern portion of the State, in the Press; more especially so for the reason that Siskiyou, Trinity and Shasta counties are, in a manner, strictly mining counties, and have been for over 30 years constantly contributing to the golden wealth of the world. Seeing your very broad and earnest solicitations for mining news in your issue of the 11th inst. from all quarters, I venture a few words from this portion of the State in its behalf.

It would seem to one who is and has been acquainted with northern California mining, its product, etc., for 25 or 30 years, and to one who has kept pace with the product of the precious metals on the Pacific coast, that northern California and south Oregon had been, in a manner, entirely overlooked. At the same time its golden treasure went forth each year to swell the worlds' riches.

The mines in this part of the State are principally placer. Although much gold has been taken from quartz, there are but few of the latter that have proved extensive as yet. Among them I might mention the well-known Black Bear Quartz Mining Co., which ranks first among the best dividend-paying mines in the State. We feel the absence of capital to open up a few more mines of this character, from the fact that the mines generally in this country are operated by many men of small means who, like all miners did in early days, took the gold from their sluices every night when their day's work was done, and when it ceased to pay satisfactory wages, it was abandoned, and a new and more accessible place was sought. In other words, whenever it required much outlay of labor or capital to open up the mine properly, it was abandoned. Such has been the condition of things in this part of the country for many years. This leaves a good large field for capital and enterprise, but there has been no one to talk it up or bring it to the notice of capitalists—another thing that has been against its advancement. Legitimate mining was a thing that few looked for; speculations in mining stocks absorbed all the attention and capital.

Things have certainly reached the turning point, and with the building of railroads through the more remote portions of the State (and the disastrous operations in stocks will certainly bring about the desired change), we shall look forward with much interest to a more legitimate state of affairs.

A friend of mine, a merchant in this part of the country, when in conversation with him, a short time ago, in regard to getting capital interested here, said when he was in San Francisco buying goods he was telling a capitalist of our resources in mines, and really got the capitalist interested; but when he informed him that to get to our country he would have to ride 125 miles over a mountain road in a stage-coach, and then take it muleback perhaps twenty to fifty more, he didn't want any of that in his; but if he could take a sleeping-car and ride to the spot, he might come and take a look at it. But capital is coming, and will continue to come; so will railroads.

Our mountain valleys here are very productive. Though small, they are well cultivated, and the product is sold at their doors to supply the mines surrounding. The supply is generally more than equal to the demand, though, as a rule, prices rule on an average with prices in the Sacramento valley.

There are several things in favor of northern California's mines that do not exist in many other mining sections. We can boast of the best watered country in the State. These high mountains hold in store a wonderful supply of snow. The streams during the summer months are torrents. These streams are not tributaries to the Sacramento river, where the debris is so much disliked, but put into the Pacific ocean direct, thereby giving no offense to the farmers nor interfering with any navigable streams. There are chances for companies with capital to operate on an extensive scale, where large returns are sure to follow. It wants enterprising men to look them up and bring them to the notice of capitalists.

Miner.

Scott Valley, March 27, 1882.

Damage from Powder.—H. A. Heywood, acting as drummer for the Thunder Powder company, and relying on the company's representations concerning its safety, tamped some of it in a hole some time last year, while trying to effect a sale in Utah, and an explosion took place. Heywood lost one eye, had the other permanently injured, and lost 15 teeth and a portion of his upper jaw, besides having his left arm badly broken. He now sues the company for $20,000 damages.

Tintic is now receiving considerable attention from mining operators. The out-put of that district will be large this season.

On the Estimation of Small Traces of Gold.

The following by Nelson H. Darton is from the *Scientific American:*

It is of considerable interest to geologists, as well as prospectors, to note the rocks containing mere traces of gold; and as they are very abundant even in this State, we often meet with them. There is a porous gneiss at Inwood, New York city, containing appreciable amounts of gold, sintered down from elevations in the north as placer deposits of very weak intensity, and become fixed in the rock. This origin is clearly shown, as there was a very gentle slope through the State, and the amount of gold, probably limited to commence with, was thus widely disseminated over this incline and there fixed by deposits above it, and came into intimate contact with the rock by infiltrating waters taking it into solution and depositing it through the mass. Fissures and basins occurring in several of the counties in northern central New York intercepted and concentrated parts in its downward movement of the richer portion of ore, and thus gave in places the rich indications and yields.

There have been a number of methods proposed to detect the minute quantities of gold occurring in the rocks mentioned above, and in ore tailings, etc.; and having examined and tested every method I have known to have been suggested, I have come to the conclusion that the one noticed below yields by far the most satisfactory results if the details are carried out, and is the most practicable in the field or in the laboratory. I know of no compound which would be formed from natural products by the method which would mislead by staining the ash a color at all similar to the distinctive purple of finely divided gold.

Small parts are chipped from all the sides of a mass of rock, amounting in all to about a quarter of an ounce. This is finely powdered in a steel mortar and well mixed. About half of it is placed in a capacious test tube, and then partly filled with a solution made by dissolving 20 grains of iodine and 30 grains of iodide of potassium in about an ounce and a half of water. The mixture thus formed is thoroughly agitated by shaking and warming, and then, after all particles have subsided, dip a piece of pure white filter paper in it, allow it to remain for a moment, then let it drain, and dry it over the spirit lamp. It is then placed upon a piece of platina foil held in a pincers, and this heated to redness over the flame; the paper is speedily consumed; and after heating further, to burn off all carbon, it is allowed to cool, and then examined. If at all purple, gold is present in the ore, and the relative amount approximately deduced, as much, fair, little, or none. This method takes but little time and is very trustworthy.

Mining Decision Endorsed.

An Iowa Hill correspondent of the Placer *Argus* says: A jollification meeting was held at this place last evening on receipt of the news of Judge Myres' decision in favor of S. B. Drury and Prof. W. P. Blake, in the mining suit of Byrnes vs. Drury. The citizens of the Hill, in order to express their satisfaction with the decision, fired a salute of 75 guns, and gave three rousing cheers each for the Judge and for Messrs. Fulweiler and Tuttle, the able attorneys for Drury; also three more for Prof. Blake.

This case was tried in the February term of the Superior Court, and the decision rendered by His Honor gives entire satisfaction to the majority of respectable citizens of this divide. It is a case which has been watched with great interest for several reasons. First, the property in dispute is a quartz ledge formerly known as the "Garrity" or "Gray Eagle" ledge (now known as the "Providencia"). It was known to have been abandoned by all former owners and claimants for the past 20 years. Drury relocated it Oct. 16, 1880, and induced Prof. Blake to invest in it, in order to develop the mine. When it was found that it was likely to become valuable property, suit was commenced against Drury and Blake.

One of the great drawbacks to this divide is that men claim large amounts of valuable mining property, who have not spent a dollar on them for the past 25 years, nor have they any legal right to them; but should parties relocate the same with the intention of investing capital to develop them, such suits as the one just decided are commenced, thereby retarding their development for years. For this reason the citizens of this divide rejoice at the just decision of the Hon. B. F. Myres.

Day Company.—The Day mine is developing into one of the richest mines in the country, containing a large quantity of high-grade ore. Work of development is being vigorously pushed ahead. They will commence repairing their furnace on the 1st of April, and it will probably start up the latter part of the month. The run will probably be for 60 days. A couple of directors of the company are expected to arrive here on or before the 10th of April, when it will be decided at what place in the vicinity of Royal City the new furnaces will be erected. We are of the opinion that they will be erected down in the valley, a little this side of the 15-mile well, where an abundance of water can be obtained beyond a doubt. The little town which will grow up in the vicinity of the furnaces will not be monopolized as a "company."—*Pioche Record.*

New Method of Purifying Copper.

Successful experiments, described in the December number of the *Comptes Rendus*, have recently been made by M. J. Garnier, at the works of Messrs. Lavsissiers et Fils, Deville, near Rouen, with the purpose of removing arsenic and antimony in the commercial copper. From a theoretical standpoint the method now generally employed might be more satisfactory. The refining hearth is covered with silica, supposed to absorb the arsenic and antimony which are oxidized during the process, and to make them go into the slag. In reality this combination is formed very imperfectly, and an amount of two one-thousandths of arsenic is considered sufficient to impair the quality of the copper.

Mr. Garnier's process in some respects resembles the Thomas Gilchrist process. He employs a sole of chalk and tar, over which, for each separate operation, he places a false sole of limestone and manganese peroxide. With the melting of the copper a generation of carbonic acid and oxygen begins from the upper sole, which oxidizes the charge. As soon as the metal is sufficiently liquid, the lime and manganese protoxide rise and dissolve the arsenic acid. By this one operation, the amount of arsenic, according to M. Garnier, is reduced to one-fifth. Subsequent fusions with basic fluxes are said almost completely to eliminate the arsenic. An analysis of a cement copper of Rio Tinto is added. Of 0.8% of arsenic, only 0.023 could be determined at the end of the third operation, the amount of iron contained being at the same time all but removed. No mention is made in this analysis, of antimony. As special advantages of this system, M. Garnier claims that the roasting of the black copper becomes unnecessary, and that the loss of copper arising from parts of the copper combining with the silica of the slag is avoided.

The Season's Prospects.

The most important consideration to people just now is the prospect of business during the approaching season, says the Bodie *Free Press*, and it may be profitable to look over the field with a view to forming an opinion upon that point. It may safely be predicted that more work will be done in Bodie District proper, during the present season, than during that which has closed. The very promising appearance of things at the south end certainly insures a continuance of operations in the mines which are now running, and the probabilities are that in other claims which have been shut down work will again be resumed. Without reference to the stock aspect of the Noonday development, which of course no one can forecast, its importance to the business interests of this community, cannot well be overestimated. Should we be so fortunate as to open a bonanza on the eight hundred level of the Bodie and Mono, or should the rich vein below the sixth level of the Bodie widen out a little as it goes down, we would soon experience such prosperity as we have not known for many a long day. The finding of ore in the thousand level of the Standard, or below, would have a similar effect. The crosscuts in Oro or Goodshaw, and the approaching eight hundred level from the Red Cloud, may either one cut an important figure in this spring's operations. In the meantime the Standard will continue to crush its twelve hundred tons of ore per week and declare its regular monthly dividends. The building of the extension of the narrow-gauge railroad from Mono Mills to Benton will employ a good many men, and a considerable amount of supplies will be purchased from our merchants in Bodie.

Outside of Bodie, mining operations to a considerable extent will be carried on in other portions of Mono county, and in the adjoining county of Esmeralda. It is understood that several strong companies will take hold of Lundy properties during the coming season, where, it may be proper to state, the most flattering inducements are held out to capitalists. The Great Sierra Co. will continue its extensive operations at Tioga district, and it is probable that some work will be done in Jordan district during the year. The camp which is likely to the attract most attention, however, and in which most extensive prospecting will be done, is Sweetwater, or Patterson district, as it is more properly called. Dr. Summers is doing unexpectedly well with his little mill, where he has an ample supply of ore on hand to last until he will be able to again work the mine. It would be gratifying to see one or two large companies engaged in Sweetwater, where there is every assurance of a great mining district.

At Aurora it is understood Governor Blasdel's milling operations are turning out quite satisfactorily, which must conduce to give that camp renewed life. The extension of the railroad to Benton and the country south will impart fresh impetus to mining enterprises in that great mineral section.

Indeed, in looking over the mining field in every direction, north, south, east and west, toward distant Idaho and Montana, Arizona, New Mexico and Colorado, we fail to note any which offers superior attractions for the prospector and for the capitalist to those which can be presented in this immediate section, embraced in the counties of Mono and Inyo, California, and Esmeralda county, Nevada.

In Candelaria, Nev., the water company sells water at five cents a gallon. Enterprising peddlers run water carts in opposition, and sell water at three cents a gallon.

Shasta County Mines.

The Shasta *Courier* says: The articls which we reproduce this week from the Mining and Scientific Press on quartz, nugget and pocket mines, is applicable to this county at the present stage of the mining boom in this vicinity, which has received fresh impetus from the discovery of the decomposed quartz strike of Brincard & Lowery, between the Gage place and Middletown, from which strike some $6,000 is known to have been realized, and also from the Zent pocket at Whiskytown from which $1,600 has been taken in a few days, and more being panned out daily. The fact is, Shasta and the vicinity surrounding the town is a most inviting field for prospecting and the investment of capital. The way the mines here, and in a radius of miles around, "pangled" in early times, bears us out in the belief that we are situated in the midst of a locality which, when the sources from which the gold already taken out are found, will be more prosperous than ever before.

At Horsetown, Muletown, Centerville and Texas Springs, innumerable nuggets and rich pockets have been found. On Tadpole, below the reservoir, an immense nugget was taken out in 1855, sold to Callahan and exhibited at his store. Oregon gulch has yielded many nuggets, G. R. Knox taking out the "boss" one in 1856. At the falls of Buckland gulch, half a mile from Brincard & Lowery's bonanza, a miner by the name of Curtiss took out $600 in two days. Nuggets worth from $1,100 down have been found in quartz at Middletown. At Salt Creek, Lower Springs and Middle Creek, countless nuggets and specimens have been taken out.

The Dannels pocket, on the hill just back of the Sweetser place, yielded a snug fortune. At Bunker Hill, at the mouth of Middle creek, mule-loads of quartz gold have been taken out, and fortunes still remain embedded there. Lucas, who owns seam diggings on the creek, takes out some very good-sized nuggets occasionally. Rock creek has always abounded with nuggets and pockets, and it was not long ago that E. L. Reese realized about $500 from a small quartz seam near the hospital. On Spring creek, several years ago, Fred Rochon and partners found a number of nuggets, the largest of which weighed $3,300, and was on exhibition here. Flat creek has, and still does, shell out the nuggets and quartz specimens. Whiskytown, Oak Bottom, Mad Ox, Mad Mule, French Gulch, etc., are just "lousy" with rich seams, pockets and pot-holes filled with gold. But we need not particularize, and only make the above mention to show that Shasta has been, still is, and always will be, the center of an extensive and very rich mineral territory. Surrounded with such bonanza mines as the Banghart, Mad Ox, Iron Mountain, Brincard, and the thousand-and-one other mines of present lesser note, Shasta certainly has a bright future before her, and all the more so on account of the activity which is now pervading mining circles here and everywhere. The old cry that the "mines are played out" is itself played out. While the Redding *Independent* exclaims, "Thank God! we have no mines," old Shasta lifts a grateful face to the throne and fervently thanks God that we do have and are surrounded with mines.

The Grand Lodge, A. O. U. W. of California, met in Dashaway hall Tuesday morning, Grand Master Barnes presiding, and a full representation of lodges being present. One hundred and seventy-four members receiving the Grand Lodge degree. The call of the roll showed a representation from all the lodges but 18, and the attendance to be about 275. The Grand Recorder's report shows that there were 3,529 admissions during the year; losses by death, 96, and by withdrawals, suspensions and expulsions, 622. The average duration of the losses was one and a half years, and the average aggregate payment of each to the beneficiary fund was about $22.50. The Order gained or saved during the year from lapsed or annulled certificates, $13,995. Only 88 of the deaths during the year were officially reported before its close. Fourteen assessments were levied during the year to meet the death calls. The causes of death were: Accidental, 13; consumption, 8; pneumonia, 8; suicide, 6; heart disease, 5, and the remainder from various diseases. The report of the Grand Receiver shows that he had received $280,000 and had disbursed $260,000 during the year. Grand Master Barnes' report was strong against intemperance, stating that it was not consumption, heart disease or Bright's disease that the Grand Body need to spend hours debating how to guard against, but that the great evil overshadowing all of these was liquor and beer drinking, which lead to all manner of diseases, as well as to accidents, suicides and murders.

The Bodie *Free Press* says: If Professor Le Conte should visit Mono county he would find at Bridgeport veins of metalliferous quartz forming, through the action of hot springs, in the plainest and most unmistakable manner. We consider the Bridgeport hot springs one of the greatest natural curiosities on the Pacific coast, and one of the most instructive, upon the subject of the formation of metalliferous veins.

Gould's Mexican railroad has been completed from Laredo to a point 40 miles beyond the boundary, and it is expected that Monterey will be reached by September 1st.

MECHANICAL PROGRESS.

Steam Boilers.

Many of the difficulties which arise in connection with steam boilers in use are not understood by engineers in general, and, in fact, some phenomena cannot be accounted for, even by experts.

The conditions under which a boiler is used have much to do with its behavior. First, is it properly constructed, and are the parts so adapted to each other that there is no undue or unequal strain brought to bear on any particular part? This may arise from improper bracing—having a greater tension on one brace than there is on its neighbor. Joints may be so constructed that there is constant distress over their entire length. If the holes for the rivets are not fair and the *drift pin* is used to bring them fair, there is an unnatural strain brought to bear that is no part of its legitimate burden, and is not provided for in the formulæ used for estimating safe working pressures. These abnormal strains are very much exaggerated when the boiler is under pressure and the load is not evenly distributed. Hence, the portion bearing the excessive load becomes a point of weakness, and how weak can never be known until leaks, ruptures, or worse consequences follow. Many boiler explosions are no doubt attributable to carelessness in construction. The responsibility, therefore, resting upon boilermakers is a very grave one.

It is not always easy or possible to detect defects in workmanship when a boiler is finished and painted over with a coating of gas-tar, or some similar material. Another difficulty is the water used. In many cases, no trouble arises from this source, while in some sections of the country there is constant and serious trouble from water carrying more or less lime or magnesia in solution, or from a combination of both with iron and other ingredients. Hard scale or crust is formed on the fire-sheets, tubes and flues and the efficiency of the boiler is greatly impaired, besides the damage from burning the iron—thus destroying its strength. Carbonate of lime deposits as a fine powder under about 180° of heat. In some sections it is so abundant that the water becomes quite sensibly thickened by it, and it interferes with the free escape of steam.—*Industrial World.*

TENACITY OF MAGNETIZED IRON.—The influence of magnetization on the tenacity of iron was studied some time since by Signor Piazoli. Iron wires were hung between two hooks and ruptured by pouring water into a vessel suspended from them. They were about 14 inches long, and were inclosed in a spiral with four windings, one over another, which were either all traversed by a current in one direction, or two by a current in one direction and two by an equal opposite current, so that in both cases the wires were equally strongly heated by the spiral; but in one case they were magnetized, in the other not. The weights required to break wires annealed in charcoal (the weight of 1 m.—3.28 ft.—of wire being G = .66 lbs.) were, during magnetization, P = 2,772 to 2,873 lbs.; without magnetization, P1 = 2,668 to 2,794 lbs. In the case of wires annealed in carbonic oxide (G being equal to 1 012 lbs.), P was 3,811 to 3,833 lbs., and P1 = 3,748 to 3,784 lbs. In the case of wires annealed in hydrogen, P = 2,837 to 2,882 lbs., and P1 = 2,778 to 2,859 lbs. In each separate series accordingly the difference P—P1 was frequently less than the difference between the highest and lowest weights required for rupture of apparently identical wires; still, the mean values in each of the 14 series were from about 1% to 3% greater for the magnetized than for the unmagnetized wires, showing that the tenacity of iron increases on magnetization.

BOILER TESTING.—The *Mechanical Engineer*, in a recent number, discourses as follows about boiler testing: "The application of the hydrostatic test, even to smaller boilers, is now considered of rather questionable utility. The cases are not rare of leaks caused by its application to old boilers that have not wept a tear since it was last used upon them, unless, perhaps, on account of accidental low water, or the sudden introduction of cold feed water in large quantities, or some other easily recognized cause of leaks in the seams or at the tube-ends. There are many boiler owners and attendants who do not think an inspection is complete unless they see the test applied at a point at least 50% above their working pressure, and there is usually a long breath of relief taken when this or a greater pressure has been borne by the boiler for an instant even, without showing evidence of weakness. But it should be remembered that the parts of a boiler may be in a state of unequal tension, when they are unequally heated. In some complicated forms, some of the parts, in resisting the effort of other unduly expanded parts, are loaded before a pound of strain occurs from the internal pressure; which is not the case when they are at a uniform temperature throughout, either high or low. Therefore, those parts that may be overloaded when a strong fire is burning in the furnace, may be under equal strain with the other parts when the test is applied."

STORAGE OF POWER.—Col. Frederick Beaumont writes thus to the London *Times*: "Attention having lately been directed through your columns to the storage of power by means of air and electricity, and it appearing from the speeches of the chairmen of certain railway and tramway companies that misapprehension exists with regard to the cost of air, I beg leave to state that air is now being compressed to 1,000 pounds on the square inch with far less cost and difficulty than has hitherto been accomplished with steam at high pressures. Independent proof of this will shortly be forthcoming from a body of well-known scientific gentlemen who have investigated and tested the matter for themselves. For locomotive purposes, the results obtained from the storing of electricity do not approach those obtained from the storing of air in the amount of force actually available for traction or propulsion. For tramways there is no doubt of the cost of air being considerably below steam, and air could be used on the underground railway at a cost in capital expenditure somewhat in excess of that for steam engines, but in daily working the expenses would be very trifling, if any, beyond the present cost of steam, while it is obvious that the difficulties of ventilation and deterioration of girders would vanish."

THE VALUE OF THE DEPARTMENT OF WORKSHOP EXPERIENCE.—"When I was a boy, I thought the assertion that "the fools were not all dead yet" implied that at some time in the future they would all die, and that all remaining would be wise men; but time and experience have changed my views in this matter. It is evident that there are ten fools raised where one fool dies—that is, supposing the investigation to relate to any one given subject. For the more people, subjects and improvements there may be, the more it is rendered impossible for any one man to be familiar with everything, hence a man wise in some directions may be foolish in many others. Especially is this the case if he is tied up to the ten or fourteen-hour system in shop work." So writes a correspondent of a mechanical paper, who is especially pleased with the interest which practical men in every branch of industry, to write their views for publication in our technical papers. He adds: "In this way, each man may tell what he knows practically, and from it all may gain information upon matters in which they are not thoroughly posted."

NAPHTHA FOR LOCOMOTIVE FUEL.—Holland's process for running locomotives with naphtha for fuel, which was so enthusiastically heralded a year or so ago, has not yet proved successful, we are sorry to say, although the extravagant advertising in advance made us skeptical about the outcome. It is now admitted that the locomotive which has for a long time been in process of construction and reconstruction, and for which such extraordinary results were promised, is thus far a failure, though we certainly hope that the experiments will not be abandoned. Dr. Holland's theory may contain the germ of success, but he has diminished confidence in it by adopting the stock advertising methods of Keely and Proseer, and promising results with only theory and crude experiments to back him. Meantime, Gen. Haupt, of the Northern Pacific road, and a few other scientific men are proceeding quietly and cautiously with experiments in the same direction of utilizing petroleum for fuel, and the entire country is interested in their ultimate success.—*Railway Journal.*

INCREASING NEED OF BRAIN-WORK IN THE ARTS.—At a recent gathering of the spinners and weavers of a large Paisley firm, one of the proprietors gave his men an account of his recent visit to this country. Speaking of the race for industrial supremacy between the English-speaking peoples of the old and new world, and the increasingly important part played by technical knowledge and inventive power in the great competition, he said: "The time was when physical exertion alone could win the battle; but in these days of scientific research, brain power is the element of success. A workman now requires to employ his head quite as much as his hands, and with every new invention physical labor will be lessened, but head labor will be increased. You cannot read too much, and you cannot study too much, and you cannot tax your powers of thought too much. Specially would I say to young men: Never consider that your present machinery is perfect; look at it rather as crude compared to what it might be."

COMBUSTIBLE ARCHITECTURE.—In an official report by Mr. Edward Atkinson and Mr. William B. Whiting, of Boston, they mention with much satisfaction the fact that more attention is now being paid to careful construction of buildings. They also state that the old stock of combustible churches, hotels, schoolhouses, hospitals and asylums is being consumed at an unusually rapid rate. In previous years this destruction has been at the rate of one church per week, and one hospital, almshouse, insane asylum or schoolhouse per month. In 1881 this was very much exceeded. In their concluding remarks they appear to think that if this rate is kept up for a few years longer, a salutary lesson will be taught, the old stock of combustible buildings be reduced and a new stock take their place more in accordance with our present knowledge of the law of fire-proof construction.

SCIENTIFIC PROGRESS.

Can Insects Discriminate Different Colors?

A few years ago, when the problem of the connection between flowers and insects still remained much in the state where Sprengel left it at the end of the last century, it would have seemed quite impossible to answer this question. But nowadays, after the full researches of Darwin, Wallace, Lubbock and Hermann Muller into the subject, we can give a very satisfactory solution, indeed. We now know, not only that the colors of flowers as a whole are intended to attract insects in general, but that certain colors are definitely intended to attract certain special kinds of insects. Thus, to take a few examples only out of hundreds that might be cited, the flowers which lay themselves out for fertilization by miscellaneous small flies are almost always white; those which depend upon the beetles are generally yellow; while those which bid for the favor of bees or butterflies are usually red, purple, lilac or blue. Certain insects always visit one species of flowers alone; and others pass from blossom to blossom of one kind only on a single day, though they may vary a little from kind to kind as the season advances, and one species replaces another.

Certain blossoms which lay themselves out to attract wasps are, as Muller quaintly puts it, "obviously adapted to a less æsthetically cultivated circle of visitors." And some livid red flowers actually resemble in their color and odor decaying raw meat, thus inducing bluebottle flies to visit them and carry their pollen from flower to flower. Down to the minutest distinction between species, this correlation of flowers to the taste of their particular guests seems to hold good. Hermann Muller notes that the common galium of our hedges is white, and therefore visited by small flies; while the lady's bedstraw, its near relative, which is yellow, owes its fertilization to little beetles. Mr. H. O. Forbes noticed on one occasion that a particular bumble-bee sucked the honey from 30 purple nettles in succession, passing, without noticing them, all other flowers in the neighborhood. Sir John Lubbock long ago convinced himself by experiments in placing glass covered with honey upon yellow, pink or blue paper, that

Honey Bees Could Discriminate Colors,

And that they display a marked preference for blue above all other colors. The fact is, blue flowers are, as a rule, specialized for fertilization by bees, and bees therefore prefer this color; while conversely the flowers have at the same time become blue because that was the color which the bees prefer. As in most other cases, the adaptation must have gone on *pari passu* on both sides. As the bee-flowers grew bluer, the bees must have grown fonder and fonder of blue; and as they grew fonder of blue, they must have more and more constantly preferred the bluest flowers.

ELECTRICAL PROPERTIES OF INDIUM.—The metal indium has always been a more attractive object for the physicist than for the metallurgist. If it were not for the two brilliant lines in its spectrum, blue and violet respectively, that helped Messrs. Reich and Richter to its discovery, some eighteen years ago, and which are still one of the favorite sights for the audience of a lecture on spectrum analysis, the general public might hardly know anything of its existence. *Engineering* says: It is so scarce, that even its prominent qualities could hardly secure it a future. The royal mines at Freiberg having come into possession of a somewhat larger quantity of indium than usual, they placed some at the disposal of Mr. Th. Erhard, to enable him to make some experiments with a view of ascertaining the electric position of this metal, but great difficulty was caused by the metal being so very soft. To ascertain the conductive resistance in the wire drawn from it, Mr. Erhard rolled it up in a coil, but he found, however, after unrolling and measuring at the termination of his researches that the wire had extended its length one-fifth of an inch, the original length being a little less than six feet. It was ascertained that the electrical resistance of indium was about eleven times less than that of mercury, and that it increased pretty regularly with a rise of temperature.

A NEW PROCESS FOR MANUFACTURING GAS IS OUTLINED AS FOLLOWS:—First, in injecting air and steam into or through incandescent coal or carbon contained in a suitable furnace, causing the air and steam to combine with the carbon, and to produce carbonic oxide and carbonic acid; the hydrogen of the decomposed steam and the nitrogen of the air being at the same time set free. Secondly, in the separation of the nitrogen from the gas by converting it into ammonia, said conversion being effected by causing it to combine with carbon and alkali, so as to form cyanogen, and subsequently decomposing the cyanogen so formed by means of steam, the product being ammonia, the oxides of carbon, and alkali; and subsequently removing the ammonia. Thirdly, in decomposing the carbonic oxide in the gas and converting it into carbonic acid by means of incandescent steam, the product of said decomposition being carbonic acid and hydrogen gas. Fourth, in the removal of the carbonic acid from the gas by means of ammonia.

THE CRICKET'S CHIRP AND THE TEMPERATURE.—The rate of the cricket's chirp varies with the temperature, becoming faster as the latter rises. Recently a writer in the Salem (Mass.) *Gazette* gave the following rule for estimating the temperature of the air by the number of chirps made by crickets per minute: "Take seventy-two as the number of strokes per minute at 60° temperature, and for every four strokes more add 1°; for every four strokes less deduct the same." In a letter to the *Popular Science Monthly*, Margarette W. Brook gives an account of observations she made with a view to testing this rule on twelve evenings, from September 30th to October 17th. Her column of temperatures, as computed by the rate of vibration, shows a close agreement with that of temperatures recorded by the thermometer.—*Nature.*

THE CARBONACEOUS RESIDUE FROM THE SOLUTION OF STEEL IN THE DOUBLE CHLORIDE OF COPPER AND AMMONIUM.—When steel is treated with the double chloride of copper and ammonium, it dissolves and leaves a carbonaceous residue. Mr. Andrew Blair, in a series of experiments, washed this residue with the above double chloride acidulated with hydrochloric acid, and finally with water, until the filtrate gave no precipitate. Then nitrate of silver was added. A careful examination of the substance then revealed the fact that it contained carbon, hydrogen, oxygen and chlorine, besides a small quantity of nitrogen. It appears probable that the carbonaceous substance is not simply a hydrate of carbon, but rather a carbon compound.

AN ELECTRIC LIGHT IN THE STOMACH.—Think of an electric light in your stomach; yet such a contrivance has been put into use lately. A fine platinum wire, rendered white hot at its extremity by an electric current, and this extremity covered by a little glass globe, is the whole machine in a nutshell. The effect is, as it were, to render the body in a manner translucent, enabling the operator to take a panoramic view of one's internal economy. We may now show the degrees of digestibility of all the patents and high grades in the market, and be enabled to sample the brand and consumer at the same time.

THE MOST DANGEROUS POISON.—The late Sir Robert Christison was the discoverer, by an experiment on himself which nearly proved fatal, of the properties of the Calabar bean, and was one of the last pupils of Orfila, the great toxicologist. At the Palmer trial, after testifying that he knew a vegetable alkaloid, the minutest dose of which was fatal, but which no test could detect in the body, he was adjured by the judge not to mention it, though he received hundreds of letters afterwards begging him for "the sake of science" to make the secret known. The poison in question was digitaline.

POSSIBLE SHIFTING OF THE COURSE OF THE LOWER MISSISSIPPI.—For some time a portion of the waters of the Mississippi river have escaped into the Atchafalaya river, a few miles below the mouth of the Red river. At a recent session of the House Committee on the Improvement of the Mississippi river, Capt. John B. Eads laid great stress upon the importance of closing this undesirable outlet, and predicted that if it were not closed the whole volume of the Mississippi would take that route to the sea.

WORK YIELDED BY VARIOUS SUBSTANCES.—In a recent lecture at the Crystal Palace, London, Prof. Sylvanus Thompson explained the theoretic work obtained by the consumption of one ounce of various substances as follows:

1 oz. of hydrogen gives		2,925,000	foot pounds.	
1 " " coal	"	695,000	"	"
1 " " zinc	"	113,000	"	"
1 " " gunpowder	"	100,000	"	"
1 " " copper	"	69,000	"	"

THERE is in course of construction at the Maryaville foundry a machine which is a combined dredger and levee-builder. It is the second of the kind ever built. The first one was made at the same establishment, and is in use on the San Joaquin river. This one is to be used in levee building on the Sacramento river. The dredge has a swing of 80 ft. The machine is capable of building a levee 40 ft. high and 80 ft. wide. It is known as the Vandegar dredger.

THERE is a rumor afloat, says the Austin *Reveille*, to the effect that the company who recently purchased the Alexander mill and mining property at Grantsville, has contracted with a San Francisco party to put in 60 stamps in the mill in addition to the 40 already in use. Another rumor is that 110 more stamps are to be added, which would make 150 altogether.

TOO MANY MEN.—Men are flocking into Bristol. Dick Walsh, Foreman of the Day Company's furnace, informs us that the town is filled with idle men, who can get nothing to do, and he knows of no prospect of them getting anything to do. His advice to people on the outside in search of employment is to keep away from Bristol.—*Pioche Record.*

THE BROOKLYN BRIDGE.—The bridge between New York and Brooklyn will be open for passenger traffic next Christmas. Latest estimates say that the cost of this mammoth structure will amount to over $2,500 per ft., or a total of $14,939,590.

The Mining Share Market.

Our stock tables show how little change has occurred in prices this week:

In the old bonanza mines they will soon he in shape to do some prospecting along the Best and Belcher line and in other sections. In this part of the Comstock there is a vast amount of unexplored ground. For a long time they have been almost wholly occupied in making air and and other connections.

At the Savage they are now pushing prospecting drifts on both the 2200 and 2400 levels, and in both they will soon reach the vein. Meanwhile they are taking out and milling a considerable amount of ore from the old upper levels.

In the Chollar and Potosi they are exploring a large section of wholly virgin gronnd, lying on and above the 2400 level. Some very favorable material is being encountered in the crosscuts now in progress.

At the Yellow Jacket and other mines that are flooded no work is being done at present, but plans for pumping ont the water are being drawn up. It is quite probable that the Belcher pump will he moved np to the Ward shaft and set to work at that point. It is the belief among those best informed, that the water will not hold out long after a determined attack is is made npon it. It is thonght that in filling np the levels of the several mines it bas about spent its force.

At last measnrement the water had risen 380 ft. above the Yellow Jacket 2300 station, and was thought to he still coming np slowly, thongh with so little strength that this may he given as the prohable point above which it will not rise materially. The committee are at work on their plan for draining the Yellow Jacket and surronnding mines.

A Enreka dispatch says: "Upon examination of the ground around the ore body in dispute, between the Richmond and Alhion, it was found to have caved hadly, and it is estimated that it will cost $25 a ton to take it out."

Assessments falling delinquent in April amount to $856,100, levied hy 27 mines, against $1,068,450, levied hy 39 mines in April, 1881, including $885,450 for Nevada, $128,000 for California, $30,000 for Idaho and $25,000 for Dakota. Of this month's delinquent assessments, Nevada mines want $791,100, California $21,000, Utah $18,000 and Arizona $26 000. The comparative statement of the assessments falling delinquent during the first four months of 1881 and 1882 are as follows:

	1881.	1882.
Nevada	$2,287,350	$2,068,800
California	630,900	436,600
Idaho	30,000	
Dakota	100,000	50,000
Arizona	78,000	118,000
Utah	9,000	22,000
Mexico	17,500	30,000
Totals	$152,750	$2664,800

THE Visalia *Delta* saya the public schools of Tnlare county have been carried on under great disadvantages, this winter, owing to the general prevalence of measles and whooping-cough, and the tendency of every had cold to develop into pneumonia. There are few districts where the teacher has not been obliged to suspend operations two weeks, four weeks, six weeks, and so on.

Discovery of Iron.

The Calaveras *Citizen* of the 8th, says: While in Sheep Ranch on Monday we learned of an important discovery—the discovery of a lode of rich iron ore. As the discoverers and locators are all residents of Sheep Ranch, we had no difficulty in ascertaining the particulars in regard to the mine. From them and others we learn the following: The lode, which oddly enough, was discovered on the first day of April, is situated two miles east of Jesns Maria creek, and crosses this creek about 400 ft. east of the Livermore Mining company's quartz mill. It extends north and sonth, and can he traced two or three miles, hut the discoverers believe that only 700 or 800 ft. of the vein is of high-grade ore. Assays have been made of ore taken from various parts of the lode, some of which yield as high as 90% iron. The average width of the lode, judging from the croppings, is about 300 ft. and is of high-grade ore throughout its entire width. The ore is called magnet iron ore, for the reason that small particles will readily adhere to a magnet. This same lode has been prospected south of the place the present location was made. The present locators were not the first to discover the lode, hut they were the first to discover the particular spot on the vein where the high-grade ore is obtained. The lode was discovered by J. H. Bray and W. B. Swank, and on April 1st it was located hy J. H. Bray, W. B. Swank and J. S. Swank, and the name appropriately given is the "Iron King."

THE SMALLEST CIRCULAR SAW in practical nse is a tiny disk about the size of a five cent nickel, which is employed for cutting the slits in gold pens. They are about as thick as ordinary paper, and revolve some 4,000 times per minute. Their high velocity keeps them rigid, notwithstanding their extreme thinness.

THE Union Pacific Railroad Co. employs about 25 traveling agents, besides an army of general agents, to give information ahont transortation and facts regarding the great West.

Meetings and Elections.

Teirakoff Con. G. M. Co., April 10. Trustees—A. W. Bishop (President), Stephen Wing (Vice-President), A. G. Gurnett (Treasurer), W. G. Gurnett (Secretary), J. C. Gore, William Antisell, H. W. Clays. Work will be resumed on this property immediately.

Bullion Con. M. Co., April 10. Trustees—Daniel Cook (President), Charles H. Fish (resident Vice-President), John F. Boyd, W. S. Wood, William Willis, L. Osborn (of San Francisco), and M. R. Cook (of New York), Vice-President.

Excelsior Water & M. Co., April 5. Trustees—J. H. Bolles, Henry W. Cleveland, H. B. Wheaton, William B. Carr and Joseph Clark. Mr. Bolles was elected President.

New Incorporations.

The following companies have been incorporated and papers filed in the office of the Superior Court, Department No. 10, San Francisco:

Hite Con. M. Co., April 10. Location, Hite's Core mining district, Mariposa county. Directors, T. J. Fitzpatrick, N. R. Hart, L. H. Pockman, R. E. Dondall and J. P. Heaney. Capital stock, $20,000,000, in 200.000 shares.

California Volcanic Water Co., April 10. Object—To purchase and locate real estate lands containing volcanic waters and mineral springs. Directors, C. A. Miller, H. Fahrenkrug, F. W. Vogelin, M. Fitzpatrick, C. Kelpe, J. T. Smith, H. Lackmann, L. Husrstel and F Runtscher. Capital stock, $5,000,000

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

ALPINE.

BULLION.—Monitor *Argus*, April 3: Isabelle G. & S. M. Co. shipped to San Francisco on last Friday five bars of hullion from the Stella mine.

ORION.—We learn from P. Onriz that it is the intention of the Orion G. & S. M. Co., of Stockton, Cal., to more fully develop the Mullen mine, of Mogul, by sinking the present two-compartment shaft to the depth of 100 ft, and drift to the ledge at that depth. The Orion Co.'s property consists of two locations, each one being 1,500 ft in length, and joining the famous Stella mine on the east; also, one location running east and west along the ridge, and connecting with the old Mullen locations, above mentioned, on the west. The history of this property is identical with many other valuable mining properties in this county, which were located during the mining excitement of 1863-64, and abandoned, the ore being considered of such a base character that it could not he reduced at a profit. A prospect tunnel was run, in 1863, across the hill. The ledge was struck 80 ft from the mouth of the tunnel, and 40 ft in depth from the surface. Ore of a rich character was discovered, and a number of tons were hauled to the quartz mill in this place, and battery assays showed $60 per ton in gold and silver; yet the milling only gave $18 per ton in gold and silver. Milling, those days, was expensive, and the owners of the mine, not knowing a process of working its ores successfully, lost money on the experiment, and the mine was abandoned and pronounced worthless. Knowing that other ores of this same character are now being worked successfully at a small cost, there is no reason to doubt that, should the Orion Co. find the ore in the 100 ft deeper than the present workings they will have one of the richest mining properties in the State.

AMADOR.

THE KELLY MINE.—Amador *Sentinel*, April 6: Through the politeness of the superintendent, W. F. Walton, we were permitted to make a thorough inspection of the Kelly mine. This mine is now owned and worked by a Boston company, who purchased it from Owen Kelly, some months ago. The mine is on Murphy's ridge, two miles south of Jackson. The ground held by the company comprises two locations of 1,500 ft each—the McKay & Love and the Kelly, the latter of which is now being worked. A tunnel has been run nearly north into the ridge a distance of 715 ft, and on the face of the tunnel the ledge is 8 ft wide, having an average width in the tunnel of 5 ft. The first crosscut is run to the west, 280 ft from the mouth of the tunnel. It has been run 161 ft. At 106 ft from the tunnel it cuts the ledge, which is 5 ft in width. The second crosscut is run in the same direction, starting within a few ft of the end of the tunnel. It cuts the same ledge found in the first crosscut 49 ft from the tunnel. This crosscut is in 105 ft, and is being run to connect with the shaft of ledge. The ore found in the tunnel is ribbon-rock, and contains a fair proportion of sulphurets, which assays $80 per ton. The shaft is now down 115 ft, and will have to be sunk about 140 ft farther in order to connect with the second crosscut from the tunnel. The ledge is 4 ft wide in the bottom, and is good-looking rock. Nearly 1,000 tons of ore are on the mine dump, and a considerable quantity of rock is on the tunnel dump. Ore can be taken from five different points in the tunnel and crosscuts. This mine can be worked very cheaply, as there appears to be rock enough above the roof of the tunnel to run the mill for several years. The ore car can be run under the chutes, filled and run out. The mill is the one formerly in use at the Montecristo mine—20 stamps, 750 pounds each—and has been erected by the veteran mill-builder, S. Brees, who is now giving the finishing touches. The mill has a capacity of running through 60 tons every 24 hours, and will be set to work, giving one of "Brees' tests," so soon as the shaft ledge is struck in the crosscut, which will be in a few days. A broom bundle will ho used to save the sulphurets. T. B. Earhart has charge of the underground work at the mine.

VOLCANO TUNNEL.—Amador *Ledger*, April 8: The Volcano Tuunel company are ruuning through immense quantities of gravel, which has every indication of being very rich. The vast body of water carries everything through the flume. Bowlders as much as a man could lift are washed through like playthings. As the blocks are of wood, although unusually stout, the passage of these howlders and debris wears them out rapidly. Some apprehension is felt ou this score. It is prohahle that before another season the wooden blocks will have to he replaced with iron riffles, to avoid troubls in the direction indicated.

DOWNS.—This mine continues to turn out handsomely the precious metal. The pitch of the ledge to the northeast necessitates the sinking of a new shaft, as every sinking in the present shaft carries them farther from the ore-body, requiring additional length of tunneling to reach the ledge, and lots of dead-work in running the cars to and from the shaft. The only remedy is a new shaft that will strike the ledge somewhere about 500 ft deep.

CALAVERAS.

GOING TO START.—*Mountain Echo*, April 5: J. C. Scribner, who has the management of the Jones mine, says that work will he resumed in about two weeks, or as soon as the weather settles. This is encouraging, for no doubt hut that the Jones mine is rich, if properly developed.

ASSAY.—John Meyers, owner of the Excelsior mine, near this place, sent three lots of quartz, taken from his claim, to Vulcare, Arizona, for the purpose of getting a correct test of the ore. Assays were made, with the following results: First lot, $89 per ton; second, $42; third, $200.

GOOD PROSPECT.—The proprietor of the Uno mine tells us that he crushed 30 lbs of ore taken from the mine at a depth of 2½ ft, which yielded about $1, or in the neighborhood of $70 per ton. As soon as the mortar is readjusted, work will be commenced on an extensive scale.

NOTES.—Oshorn & Co. are still running their hydraulic, and are washing the surface off the Gold Hill quartz mine. The ground sluice prospects well, and a big clean-up may be expected. One of the company has been doing some work in the quartz, which has proved very satisfactory. He collected a pan of ore and crushed it in a mortar, and it yielded the neat little sum of $60. The Rasherry Bros. are making preparations to sink a shaft on their mine. They are down now about 10 ft. The vein is from 12 to 15 inches in width, and the average yield of the ore by the arastraing process is about $12 per ton. It is the intention of J. T. Fletcher & Co., to sink a shaft on the south end of the Confidence mine. The mine has been thoroughly tested, and it is a well-known fact that the ore is of a high grade. Mr. Fletcher has the money and the energy to carry it through.

EL DORADO.

GRIZZLY FLAT.—Cor. El Dorado *Republican*, April 6: The Mount Pleasant has got started for a long run, on good rock. The Mount Pleasant, to this camp, is the same as Standard to Bodie, or Idaho to Grass Valley. All mining camps have their best mine. I am satisfied that depth will develop some good mines. On the 400-level of the Mount Pleasant they have a vein from 2 to 12 ft thick; in the face of the drift it is a perfect glitter of sulphurets. I have seen a great many good mines, but this one is the best I have ever seen. We all expect a boom here this summer. All the miners are prospecting. All we want is money, pluck and energy, to make this a big camp. I had a talk with an old settler, who has been here for 30 years; he says the prospects have never been so flattering as they are now. I hear some talk of the Arctic starting up. They have a good property. Times are very lively at the Drieshach mines. We are all in hopes they will get two good mines there. There was some very rich

rock taken from those mines in the early days. The Treat will resume work as soon as they can get machinery on the ground. Mr. Spencer is in town, and as soon as the snow goes off will commence crushing rock from the Grouse gulch mine. The old Eagle is shut down. What a pity it don't change hands. The old company is always trying to find the mine on top of the ground, and all the experts here think it is down below. Mr. A. H. McAfee owns the south extension of the Mount Pleasant, and calls it the Ohio. He has done some work on it. It is a valuable location. The Gallagher drift gravel mine has been running all winter, and have got out considerable dirt. Major W. H. Houghton and some other Sacramento parties own the Hattie mine. They have sunk a good shaft on it, 50 ft deep. I am told the rock assays up high, from $180 to $330. Mr. Jeffries owns the Cousin Jack, at Henry's Diggings, and has done considerable work on it, and it looks well.

A Good Prospect.—*Mountain Democrat*, April 8: On Wednesday evening last we were shown a specimen of quartz and some quartz gold, the result of that day's prospecting on a ledge now being opened up by Messrs. Duncan, Johnson and Gray, on Poverty Point, near this city. There is every indication that they have a good ledge, and we shall have more to say about it from time to time as it is developed. It is an extension of the old "shepperd sandstone ledge," which is traceable for more than ten miles, and which yields a fair prospect at almost any point.

The Æna Mine.—Friend Kohlert was down from Fairplay on Monday and Tuesday of this week, and exhibited some remarkable sulphurets, taken from the Æna mine, located about 6 miles from Fairplay. The vein matter, on which the mill is now steadily running, pays upwards of $40 per ton.

INYO.

To Work Tailings.—A company, consisting of Messrs. Ward, Thorpe, Clinton and Todd, has taken hold of an enterprise on Kearsarge mountain, for which the best results is to be hoped. They will refit the old Pioneer mill, in the old town of Kearsarge, for the purpose of working the tailings at the reservoirs of the Kearsarge mill. In pay for them, the enterprising workers have contracted to sink a 50-ft shaft in the lower tunnel of the Kearsarge mine.

Panamint.—The Inyo Con. Co., at Panamint, is reported to have out some 500 tons of ore, assaying from $250 to $500 per ton. The work of extracting ore is constantly going on, but the mill will probably not steam up before the 1st of June.

A New One.—Mr. Melinda, one of the Mexicans prospecting in Beveridge, last week found a rich gold ledge at a point north of the Keynot, near Taylor's canyon.

The Keynot.—From William Ritchie, who has been working in the Keynot mine, we obtain a good report of the present condition of that solid and reliable gold-producer. He says that Supt. Miranda is working 28 or 30 men in all, including packers, surface men, etc. About 350 ft of the face of the ledge has been opened for taking out ore or tunneling. Stoping is going on in a 4-ft body of fine ore. The winze in the lower level is all in rich ore.

To Start.—The Keeler City mill, it is reported, will start up in 3 or 4 days, on Palma ore, under the general management of the lessee, Supt. Wheeler. Capt. Keeler is engaged in repairing the Cottonwood flume, and is making extensive preparations for getting out timbers, wood and coal. He intends fitting up a steamer, probably the old *Bessie Brady*, for transporting such supplies across the lake.

The Freeborn Canyon Mill.—Taylor, McEvoy & Co.'s 5-stamp mill, in Beveridge district, made a clean-up during the past week. In 20 running days it crushed 192 tons of Keynot ore, which yielded close on to $11,000, in gold. In some 4 or 5 days Supt. McEvoy will start up the mill again, on a lot of about 100 tons from the Losano mine, which is situated about 1 mile south of the Keynot.

NEVADA.

Buelow.—*Herald*, April 4: Only two men are now working in the Buelow mine, near Newtown. Some time last year the mine was hooded to a company, and a tunnel run into the hill a distance of over 400 ft. Recently the company ceased work. The ledge was tapped when the tunnel had been run 350 ft, and crosscuts were then made to determine the extent of the vein. We were yesterday shown some specimens of rock taken from the face of the tunnel, at a perpendicular depth of about 125 ft from the surface. The quartz presents well in rich-looking sulphurets, and the general character of the ore is good. The ledge is 3 ft wide and in slate formation, with a thickly sulphureted selvedge. There are two ledges on the Buelow property. On the upper one, known as the Buelow Consolidated, a shaft was sunk 142 ft, when a "horse" was encountered. The ledge in the shaft was about 2 ft wide, and rock taken from it assayed as high as $202 per ton. By mill process, without the sulphurets, $28 per ton in free gold was obtained. No work has been done on the upper ledge for about a year. We understand arrangements will soon be made to resume work at this mine on a more extensive scale.

Wide West.—There are 50 tons of quartz on the dump of the Wide West mine, at Canada Hill, which will be hauled to Crosby's mill for crushing, in a few days. As soon as the rock is taken away, the present hoisting works will be torn down, and new works erected over the new incline now being sunk, about 30 ft from the old one. The new shaft is down 60 ft, in the bottom of which there is a foot ledge, of good-paying quartz. The owners of the Wide West feel very sanguine over their prospects.

PLUMAS.

The District.—Greenville *Bulletin*, March 20: Items of interest to the mining community have been few during the prevalence of the late storms. The operations of so many mines being dependent on the water supply, the condition of the Round valley reservoir becomes a subject of deep concern. Since the storm passed, water is making rapidly; the snow is now fully saturated, and in a day or two water will be flowing into the lake much faster than it can be used. In less than a week the ditch will be carrying a full head of water. The extensive improvements being made on the reservoir by the water company are now far toward completion. The embankment is raised nearly 3 ft, and will be continued till that hight is gained. It is cribbed and strengthened in the most solid manner. The supply-pipe has been extended into the lake, beyond the new portion of the embankment, and a water-gate put in, so that the water can be shut off, and any needed repairs made to the pipe, within or below the dam. This is a very important improvement, and one that was much wanted. Formerly the water could only be shut off below the dam, and had any repairs been necessary the reservoir must have been emptied to do the work.

Cherokee.—The Cherokee company's mill has been able to run about 10 stamps for a few days during the month. After the first of the month they will be able to make full time with the entire battery. The new plank road from the mine to the mill is now opened and ore-hauling commenced. The mine continues to open out good ore.

Green Mountain.—The mills of the Green Mountain company had just started up, with about 35 stamps running, when the storm blocked the ditch, and compelled them to hang up again. They will have plenty of water to start up once more by Saturday.

Southern Eureka.—At the Southern Eureka mine the roads have been blocked with snow, so that no ore could be hauled to the mill, compelling them to hang up their stamps for some days. On Saturday morning the mill was started up again, and is now running as usual. Some very rich ore has lately been struck in this mine.

Indian Valley.—The Indian Valley company's mill started up on Saturday afternoon, and is now running at its full capacity. The hoisting works were not stopped at any time during the storm, and work in the mine went on as usual. This company will soon use water power for working their mill.

Cook's Canton.—The water has now started to run in Cook's canyon, and gravel mining will begin there in a few days. There is more snow on the slopes of the mountains around the canyons in that section than has been seen in 15 years.

Light's Canyon.—Last fall mention was made of a ledge having been found by Morton and Jackson in Light's canyon. When placer mining stopped for the season they went steadily to work on the ledge, and have continued all through the winter, until at the present time a very promising vein of gold quartz is opened up.

Rich Silver and Iron Ores.—It is commonly believed that there is no silver ore in this district, but like many other common beliefs, this turns out to be an error. Some weeks ago, specimens of what was thought to be silver ore, were sent to a perfectly reliable authority for assay. A report has just been had from the assay that one of the specimens sent contains 54 ounces of silver. A trace of gold was also found in the ore. Along with the silver ore some specimens of iron ore were also sent. This the same authority pronounced to be specular iron ore of the finest quality; and says, further, that if facilities for working it are found near the ore, we have all the essentials of a great iron industry. The immense value and variety of the resources of Plumas county are only beginning to be understood.

SHASTA.

Eagle Creek.—Cor. Shasta *Courier*, April 8: The mining interests (the placer mines) are hardly worth mentioning, as there are but very few around here, and what there are pay poorly. Quartz is receiving particular attention. There are more men at Sunny Hill this spring than there has been at any previous time. Peck & Dutton are taking out good rock and making preparations for starting their arastra. Mr. Frank Ballou is taking out plenty of rich rock from the Flower of Sunoy Hill. He is building a new trail to haul his rock over. He intends to start his arastra before long. Mr. Jacob Murray, one of our merchants, owns the mine known as the Lost Buck. He is having a large double-bed arastra constructed; also has a crew of men digging a ditch to bring water around to run the arastra. There are several other parties prospecting, but have not as yet developed anything to justify them in putting up any sort of a mill. The most of them, however, feel confident of success.

SIERRA.

Flattering Prospects.—Sierra *Tribune*, April 6: The St. Louis mining company, who are operating between Gibsonville and La Porte, recently struck blue bed-rock, and a very good prospect in blue gravel, although not as yet in paying quantities. They are still pushing their tunnel ahead, and with a very flattering outlook.

Work to be Resumed at the Lafayette.—Supt. T. H. Smith says work will be resumed at the Lafayette Hill gravel claim as soon as the roads will permit of getting in the necessary supplies. One of the members of the company is expected out from New York in a short time.

TUOLUMNE.

Another Big Enterprise.—*Independent*, April 8: Mr. J. G. Divoll, who has taken out so much money from the Bonanza mine, in Sonora, is opening up a large gravel property 2 miles in length, situated between Jacksonville and Steven's Bar. The gravel is near the combination of claims owned by him, known as the Yosemite and Grand Rapid quartz claims, on the mother lode—both valuable properties. The gravel which has been discovered is a river channel, formerly the course of the Tuolumne river, and never having been interfered with by the honest miners. A ditch has been surveyed to bring free water to the mines—the source being the Tuolumne river, which carries water enough the year round to furnish all the mining properties in the State with abundance. The water will also be utilized for mining machinery to the proposed quartz mill, which will be furnished with not less than 50 to 100 stamps. Mr. Divoll assures us that the project will be carried through; he has the coin to do it—and it is well known that when he starts into a project in earnest he has never failed. He has spent several months with a force of men prospecting and making preliminary arrangements to carry the project to a successful termination, and is now thoroughly convinced that this enterprise will turn out a second Bonanza, and even far exceed his former, and prove to be a lasting one for years to come.

NEVADA.

WASHOE DISTRICT.

Sierra Nevada.—*Enterprise*, April 9: On the 2700 level main north drift No. 1 has been extended 27 ft, and main north drift No. 3 has been extended 15 ft. The joint Union Con. east winze has been sunk 10 ft.

Union Con.—On the 2700 level east crosscut No. 1 has been extended 22 ft. The joint Sierra Nevada east winze has been sunk 10 ft. In the main lateral drift are engaged in casing timbers. On the 2500 level are stoping out ore. The engine and cage are in place at No. 1 winze, and the 2600 north drift started. During the week 486 tons of ore were extracted, and 684 tons and 1,070 lbs. have been sent to the mills.

Union Shaft.—Are putting in a pump bob at the 2,600 station and repairing the drift to the Mexican winze.

Utah.—Timbering and repairing at the head of the incline.

California.—On the 2700 level the main south lateral drift bolo has been extended 205 ft, and joint Con. Virginia east drift No. 2 has been advanced 31 ft.

Con. Virginia.—On the 2700 level joint California drift No. 2 has been advanced 31 ft.

Mexican.—On 2700 level the main north lateral drift has been extended 20 ft, the main south lateral drift the same.

Ophir.—During the week bullion to the value of $10,059.85 has been shipped.

Alta.—During the past week the north lateral drift, 2150 level, was extended 18 ft, and the south lateral drift 24 ft. Both drifts are in hard porphyry outside the vein, where we occasionally cut stringers of fair ore.

Yellow Jacket.—The water to-day stands 370 ft above the 2300 station, having risen 3 ft during the past 24 hours.

BRISTOL DISTRICT.

The Mill.—*Times*, April 4: At the Bristol mill everything is running along smoothly as usual. Are now roasting the ore again on account of it being a little more base than formerly. A large amount of good rock is daily coming down, and the bullion output for March will foot up to a good figure. The company has let a contract to put the well down another 100 ft, and when done a water necessary will be obtained for running the mill. The Day mine has probably the longest and the crookedest smoke stack in the United States. It is 471 ft long with 27 different twists and turns, running through all the upper drifts and levels from the hoisting machinery in the tunnel to the surface. How is that for a stack, and where is its equal? Heavy hoisting machinery is to be put upon the Pay Day, with a sinking capacity of 1,000 ft.

COLUMBUS DISTRICT.

Northern Belle.—*True Fissure*, April 8: A set of station chairs has been put in the shaft at the new station on the 5th level. The adit and the levels above present about the same appearance as last week and continue the usual production of ore. Sixty tons of ore are being extracted daily and sent to the mills, both of which are running steadily and doing the regular amount of work. A shipment of bullion amounting to $6,558.62 was made on the 6th inst. The total shipments of bullion on March account aggregate $67,308 85.

Mount Diablo.—The stope above the east drift on the 3d level shows a larger body of ore than at time of last report, and the prospect at this point is encouraging. Near winze No. 1, on this level, a ledge of high-grade ore is being worked that looks very promising. The stope near the center of the mine, below the second level, continues to open well and the outlook at this place is very good. The stope east of the shaft has been discontinued, the ore as found being of a very poor quality. Shipments of bullion were made on the first instant amounting to $8,435.43; and on the 4th instant amounting to $8,988 25. The total production for the month of March was $68,845.46.

East Mount Diablo.—The north crosscut is in 27 ft, the face being in favorable working ground, which is improving each day. A crossent has been started south and a turntable put in at the point of intersection with the drift.

Gen. Jackson.—The work of extracting ore still continues, the output being equal to that of any previous week. A deposit of first-class ore was struck recently and appearances would indicate its opening well.

CRABB DISTRICT.

Free Milling.—Esmeralda *Herald*, April 8: Without doubt this new field for the prospector and capitalist will receive its share of attention this summer. The ore of the district is free milling, mostly gold, and from samples assayed is shown to be very rich. Here is an assay of a sample taken from near the surface of one of the claims there recently: Del Monte assay office, March 25, 1882. Sample of ore deposited by M. M. Glenn gold $728.51; silver, $3.77; total, $727.38.

ESMERALDA DISTRICT.

The Cortez Mine.—Esmeralda *Herald*, April 8: Capt. Eudey, who for two weeks has been making an examination of the Cortez mine, left for San Francisco last Thursday. Before going he called at the *Herald* office to bid us good-bye. He said he had made a thorough examination of every portion of the property, estimated the amount of ore and taken samples of the same and forwarded them to the home office of the company in New York, and would take with him to San Francisco duplicate samples to be assayed there. He expressed a belief that the company would start work again on the mine, but could say nothing definite until returns were received from the samples sent them. Capt. Eudey says also that in his last examination he is more pleased with the mine than before. Should the company decide to resume work, it will probably be a month or 6 weeks before anything will be done.

LEWIS DISTRICT.

The Starr-Grove Attachro.—Lewis *Herald*, April 5: The Starr-Grove mine, offices and other buildings, were attached Friday evening by J. Hill for the sum of $7,784. The company has not paid off for two months. A great many miners have been thrown out of employment; most of those who were working at the mine have families, and many have just built themselves dwelling houses, while some have lately brought their families from distant points. If they should not be able to recover their wages it will entail great hardship among them.

The Betty O'Neal.—The Betty O'Neal mine is still turning out the usual amount of ore—between 6 and 7 tons per day. The south drift still improves. A stope is being opened up on this level, and men will be put to work stoping in a few days. About 230 tons of ore are now on the dump ready for milling. The ore is all first-class, and when run through the mill will turn out bullion fast.

Notes.—The ore from the Morning Star mine is being brought down at the rate of about 4 tons per day. A new road is being constructed to the Betty O'Neal mine; the grade will be more gradual than the old grade. A contract has been let on the Morning Star mine to Messrs. Sweet & Oreives to sink the Morgan incline. The Dahlgren Mining Co. has considerable ore in the Eagle mill, but is waiting for the management to make some arrangements for working their ore.

SANTA FE DISTRICT.

The Gold Bar.—Esmeralda *Herald*, April 8: This mine, situated in Santa Fe district, is turning out some rich ore. The ledge is small, averaging only 18 inches, but that is big enough when the lowest assay is, $110 while the highest runs up to $770 per ton. The incline shaft is about 50 ft down. The mine is owned by Adam Glasser, Jos. Gruber and John Fagan.

ARIZONA.

Bullion from Dos Cabazas.—*Gold Note*, April 5: Among the lots of ore recently worked by the Cincinnati & Pittsburg Milling Co. were 30 tons of rock from the Mina Chiquita mine, at Silver Camp, owned by Messrs. Fitch & Lynch. This mine has only been worked a short time, and thus far it can be called nothing but a mere prospect. The 30 tons were taken out while sinking a shaft, and cannot be considered more than a fair sample of the ore contained in the mine. The clean-up netted over $5,000 to the owners.—not a bad showing for rock extracted while sinking. The picked specimens were all sacked, and have not as yet been worked. The mill is now running on ore from the Juniper mine. This immense gold mine was leased a short time ago to Thomas Hatton, Wm Hanmore, John Casey and Fred Plum, all experienced miners and energetic men. A force of men was immediately set at work, and since then operations have been strenuously pushed forward. About 100 tons have been worked, which cleaned up $40 to the ton. Before a general clean-up is made, however, 300 tons will be worked. About 25 tons are run through every 24 hours. There is little doubt that all of the ore will average $40 to the ton, and it is thought the boys owning the lease will realize from their efforts, in the 6 months' time it has to run, the handsome sum of $60,000. They are all deserving men, and their numerous friends are much pleased at the prospect of their good fortune. Ore is coming in so fast from various mines that the mill is unable to receive it. Contracts are being made months ahead, and 3 or 4 custom mills, as large as the present one, would be kept constantly running for years to come, if they were on the ground.

A Bonanza Struck in the Juniper.—Last Thursday morning the miners at work on the famous Juniper mine made a strike that will fully establish its claim to the best and largest gold mine in the world. The shaft has been sunk to a depth of 50ft. A drift has been run in on the ledge about 40 ft from the bottom of the shaft, easterly. While at work in this east drift a vein was struck, about 2 ft in width, the ore from which runs from $400 to $2,000 per ton. This is a lucky strike for the boys who hold the lease on the mine. The point where the rich vein was struck is about 100 ft from the surface.

Ayer Camp.—From Mr. S. Porter, a prominent merchant of Dos Cabazas, who visited the above-named camp, in the Chiricahuas, last week, we glean the following particulars: The new smelter of the Chiricahua M. & M. Co. is admirably located, about 1 mile distant from the principal mine, in a canyon through which winds a stream of running water. An abundance of timber lots the surrounding hills. The water runs into the smelter, so that no pumping, is required. No expense or time has been spared to procure the most improved machinery. Several hundred tons of high-grade ore are on the dump at the mine, and the prospect appears flattering. The smelter commenced running last Wednesday.

IDAHO.

Ore Body in Mayflower.—Wood River *Times*, April 5: Last Saturday evening a new ore body was uncovered in the Mayflower mine, at Bullion. This strike was made in a crosscut run from the 50 level of the new shaft, which has been sunk since Supt. Havens took charge of the mine. This shaft was started last summer by Colonel Wall, and sunk 8 ft. As the appearance of the formation did not suit, the shaft was abandoned. When the new company obtained control of the mine, Supt. Havens erected his steam-hoisting works over the shaft, and sunk it to a depth of about 60 ft. He then opened a level at the depth of 50 ft, and soon began to crosscut the ledge. After driving about 20 ft, galena was discovered, but in loose bunches, and accompanied with carbonate ore. Soon, however, a seam or two was cut into, and yesterday morning, when the *Times'* reporter left Bullion, the ore-vein showed to be 7 ft in width, and had every appearance of being still wider.

Sloo Mine.—Wood River *Miner*, April 5: The Sligo mine, the eastern extension of the North Star mine, was bonded last week to a gentleman of this city for 30 days at $20,000. A force of men has been put at work on the mine and will develop it as rapidly as possible until a sale is effected or the term of the bond expires. The property was located by Martin Freeman, John Faley and Harry Billeny. A large vein of high-grade ore has been uncovered, and the mine is at present a very promising one. The rich body of ore found in the North Star extends through the Sligo claim,

The Open Season.—For four long, consecutive months the inhabitants of Wood River have been surrounded by snow, varying, according to place and circumstances, from 2 to 15 ft deep, and with the exception of merchants and a few mechanics, the people have had very little to do but to watch and wait for the coming of spring. Many have been despondent, and expressed fears for the future of Wood River, while others have openly attempted to give away the country by furnishing outside papers with exaggerated reports of the condition of things in general. Fits of "the blues" attacked almost everyone, but now the scene has shifted. An early-rising, genial sun is rapidly transforming the mountains of snow into creeks and rivulets, which, following the natural courses, are speeding away through the great Snake and Columbia rivers to the peaceful ocean lying far to the west. The merry feathered songsters, the first heralds of spring, are once more with us, and the heat of old Sol's rays is warming the hearts of humanity in general, in those parts. New faces are met everywhere along the river; the merchant has abandoned his late morning nap, and is seen bustling about, overhauling his goods, for the purpose of making his place more attractive to the customer; the hotels and lodging-houses are being rapidly filled; an unprecedented impetus has been given to building in this city; the seeker after employment, so long idle, has all the work he can attend to.

MONTANA.

The Original Butte.—*Inter-Mountain*, April 5: For some time it has been known that the Original Butte is looking remarkably well in the drift extending west from the 200 level of the Gagnon. The ore body assays high in silver, carries a heavy percentage of copper and is well defined, clean and compact. The ore body at present varies in width from 7 to 9 ft, and sample shipments made to the Colorado smelter have yielded very satisfactory returns. But while these explorations on the 200 level have been so actively progressing, the deeper development of the mine has been going forward with no abatement of energy. The 300-ft south crosscut has been driven 175 ft, passing through the vein to the hanging wall, along which a drift west has been extended 28 ft. Up to within the past few days the ore at this depth was found in pockets and irregular streaks, but as the drift advanced the vein became more compact and uniform, and to-day presents a very satisfactory appearance in the face, where it shows a solid ore breast fully 4 ft across and still increasing.

A Concentrator Being Erected.—Down on the flat, a few hundred yards from the depot, is a piece of land recently bought of Wm. Owsley for $1 500, by John Loogmaid. On this property the latter is now erecting extensive concentrating works, in which he proposes to treat 40 tons of copper ore per day. The Shakespeare Parrot mine is a far more valuable property than it is generally supposed to be. The lower workings show fully 7 ft of ore, some of which assays from 35 to 60 copper. A considerable amount of this grade of ore has been shipped in a crude state to Baltimore and has paid a handsome profit. The lower grade of ore, of which a vast amount is available for extraction, requires concentration before it can be shipped to advantage, and it is to meet this requirement that Mr. Longmaid is now erecting his works. It is more than likely that a smelter will also be built, as the mine has doubled in value and productive capacity since it was sold for $30,000 a few months ago.

NEW MEXICO.

Sold.—*New Southwest*, April 5: Mr. Henderson has bought from John Black, the Silver King, in the Bullard Peak district. Price, $2,000. Mr. Henderson has sunk 2 shafts of 24 and 21 ft deep, and has a drift besides.

Carlisle.—The development work on the Carlisle mine at Steeple Rock is being forced ahead as fast as 3 8 hour shifts can push it. The 3 shafts are down about 50 ft, and are making from 2 to 3 ft every 24 hours. They are all in ore that assays about $28, and up to the present everything is satisfactory. Manager W. A. Farrish appears satisfied with the prospect, but will probably go down 100ft on each shaft before he gives any decided and definite opinion.

Sherman.—Manager Henderson is pushing the development work on the Sherman, and will soon commence milling ore. The main working shaft is now down 72 ft, and, judging from the present dip of the vein, will cut the ore body at a depth of about 250 ft. The vein is from 2 to 8 ft thick, and the ore runs all the way from $20 to $100 to the ton.

It is just four weeks ago since J. C. Woodward & Co. bonded to C. O. Pearce the Mollie S., Capt. Kid and Star of Empire mines. The latter said three, along with 4 other adjacent properties, to J. K Cooding & Co., of Socorro, and the latter at once put on a force of men. To-day there are 28 men on the pay-roll; about 325 ft of shafts and drifts have been excavated, and from them have been taken and shipped 75 tons of good ore.

The Mimbres M. Co.—The Mimbres M. Co., of Georgetowo, have 250 men on the pay-roll. Col. Robinson, the superintendent and general manager, is developing the property in a thoroughly systematic manner. The company owns 8 claims, known as the Uncle Sam, Lou, MacNulty, Naiad Queen, Satisfaction Extension, Glammorgan, Lucas, Hague, and a fractional part of the original Satisfaction claim. They cover an area of 20,000 ft in length and 6,000 ft in width. The company owns one of the most complete 10-stamp mills in the Territory, which has 8 pans, 4 settlers, 1 agitator and 2 Frue vanners. They have shipped $350,000 in bullion since they came into possession of the property, and their ore averages about $60 to the ton.

OREGON.

Notes.—*Sentinel*, April 8: The pipes and both giants at the Sterling mine were moved this week and the Superintendent, Mr. Ennis, thinks the pipes will not have to be moved again for several years. The water will probably hold out at this mine until August.....Enquiry is being made for samples of ore from the "Yank" ledge by parties in Portland who desire to test it.....The English company and Bluo Gravel, on Galice creek, are both running with full heads .....Cin Len is still running 2 giants. His ground is as rich as formerly but not so profitable on account of increasing difficulty in moving it. .....A $14 nugget was picked up on upper Applegate last week.....There are now a number of men prospecting on the Coleberry fork, of Applegate.....Dick Cook is still pushing his tunnel on the famous Steamboat ledge. The quartz is beginning to show a little free gold occasionally.....Small quantities of dust continue to come in from the small mines, but the mining season in short gulches will soon be over.....Wimer & Simmons of the rich Waldo claim are working night and day without interruption, but do not expect to clean up before fall.

UTAH.

Lolu.—Southern Utah *Times*, April 8: Work on the Lulu is being pushed ahead, and the drift continues to look more favorable for ore as it advances.

The copper mine belonging to the Mahoney Bros., in Cactus gulch, is looking well. They have started up work on it, and it is reported that a body of high-grade ore has been struck.

The Horn Silver Co. is sinking a prospecting shaft near their west line, and it is now down over 100 ft. The claim joining on to the Horn Silver at this point is the Dives, which is to be thoroughly prospected this season.

Work is being pushed ahead on the Comet with gratifying results. The ore continues to get bigger as the tunnel goes in. The owners are confident that a reasonable amount of work, properly directed, will show up big.

The motion of the Star route case defenders will probably be overruled and the cases set for the last week of this month. The trials will last two months. Attorney-General Brewster has given up his project of managing the Star route cases in person, and will rely on Mr. Merrick, giving occasional encouragement by his presence in the court-room when convenient.

Wheat Cleaners.

The use of wheat cleaners attached to thrashing machines is becoming general, and farmers are demanding, more or less, that thrashers thrashing for them should use them. It will not be long before they will be as indispensable to a complete rig as the cook-house has become, owing to the system that is being rapidly perfected here to strictly grade all wheat put on the market. The result cannot but inure to the reputation of California wheat abroad, and we welcome them as great auxilliaries in elevating the standard of our wheat exports.

The advantages of a cleaner are not all on the side of the farmer, as it enables the thrasher to relieve his separator by using a coarse sieve, lowering the wind blast and let the cleaner do the rest of the work, thereby avoiding the one great trouble of blowing grain over the shoe into the chaff pile.

We illustrate on this page a new wheat cleaner, the invention of G. W. T. Carter, of Byron, Contra Costa county, whose plant of thrashing machinery was illustrated and described in the PRESS Nov. 19, 1881. Mr. Carter used several of the cleaners now in the market last season with his machines, but found them, as others have, so deficient and troublesome, that he set to work to make a cleaner that would do his work rapidly and satisfactorily. In the construction of his cleaner he has aimed to overcome these troubles, and now offers to his brother thrashers, a cleaner which he assures us runs smoothly and quietly; does not require constant attention to keep clean, nor half the crew to put it in position. It is built on the ordinary header gear, so it will keep in the road and handle easier than when the wheels are 8 feet apart.
